SURGICAL TREATMENT OF DIVERTICULITIS OF THE COLON

Carl P. Schlicke, M.D.
and
Arch H. Logan, M.D., Spokane, Wash.

Facts potentially useful in the diagnosis and treatment of diverticulitis of the colon were sought in a study of 70 patients in whom that condition was found at operation. Forty were men, and the youngest patient was 39 years old. In 16 the symptoms were acute; in 19 there had been intermittent trouble for years. Symptoms varied, and there were 18 patients in whom none of the symptoms was gastrointestinal. In 14 the preoperative diagnosis had been neoplastic disease of the intestine or pelvic organs. Leukocytosis was present in only half of the patients; the same was true of fever. Gross bleeding occurred in 13. Roentgenologic examination did not always distinguish between presence and absence of inflammatory changes, and in 11 instances the radiologic report was decidedly misleading. In 62 patients the lesion involved the sigmoid colon; in 35 of these it was treated by primary section and anastomosis. The experience of the authors with this operation has been favorable, and they urge that it be carried out, when appropriate, before serious complications can develop.

MOST studies of diverticulitis of the colon come from the large teaching centers. Their leadership in developing a more aggressive and radical approach to the problem is well recognized. No longer is surgical treatment carried out as a last resort, as a lifesaving measure, or only when dire complications develop.[1] There is an increasing trend toward offering it early to patients failing to respond to medical treatment.[2] In addition, since the advent of antibiotics and chemotherapeutic agents, an attempt usually is made to remove the diseased segment and not simply to bypass it.[3] Stage operations are seen with ever-decreasing frequency and with progressive shortening of the interval between stages.[4]

Material and Methods

Records of all patients operated on for diverticulitis of the colon at Sacred Heart Hospital from Jan. 1, 1951, to Dec. 31, 1957, were reviewed by us. No attempt at long-term follow-up was made as we were principally interested in accuracy of diagnosis, procedures carried out, and postoperative complications. Seventy patients provided the basis for this study.

Principal locations of the inflamed diverticula were the cecum in 5 patients, transverse colon in 2, entire colon in 1, and sigmoid colon in 62. Since the active disease process which led to operation was confined to the sigmoid colon in the vast majority of patients, it is this group to which closest attention has been paid in this study.

There were 40 men and 30 women. The youngest patient was a man aged 39 with a perforating cecal diverticulum, the oldest an 87-year-old man with

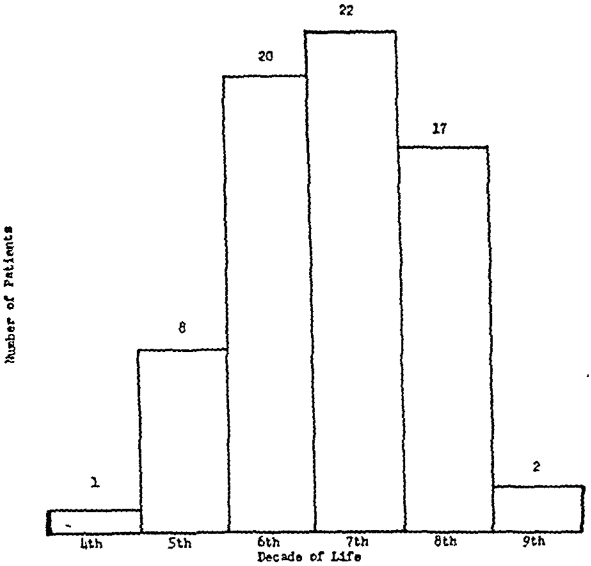
perforating sigmoid diverticulitis. The distribution of patients according to age is shown in the figure.

Symptoms

In patients whose involvement was in segments of the colon other than the sigmoid, symptoms were, with one exception, acute and of a few hours' to a few days' duration. Patients with sigmoid diverticulitis exhibited considerable variation in the duration of their symptoms. In 16 patients symptoms were acute and measured in terms of hours or days. In 13 patients duration was measured in weeks, in 11 it was measured in months. Nineteen patients had had intermittent trouble for years, manifested in some by vague, ill-defined complaints and in others by recurrent, acute flare-ups often requiring repeated hospitalization. Three patients had no symptoms to suggest the condition, which was discovered at operation.



Age distribution of 70 patients with surgical treatment of diverticulitis of colon.

In patients with lesions of the cecum and transverse colon the uniform complaint was pain localized to that portion of the abdomen containing the disease process, with the exception of one patient with a transverse colon lesion whose symptoms were obstructive in character. One patient with involvement of the entire colon was admitted because of a massive gastrointestinal hemorrhage. Forty-nine of the 62 patients with sigmoid diverticulitis complained of pain, but definite localization was less constant. Other complaints were of constipation, 16, with obstipation in 5; diarrhea, 8 patients; and nausea and vomiting, 7 patients. Thirteen patients had noted the passage of bright blood per rectum; in 9 this was of some magnitude, but in only 4 was it associated with anemia. Four of the patients who had bled had no other complaints whatsoever. Seven patients gave a history of chills and/or fever. In five patients bladder symptoms were predominant. A few patients complained of bloating, weight loss, and general indisposition. Eighteen patients had no symptoms whatsoever referable to the gastrointestinal tract.

Findings

The five patients with cecal lesions had tenderness localized to the right lower quadrant; four had fever; and a mass was noted in one. Both patients with transverse colon lesions had tenderness over the lesion; in one, a mass was palpable. No findings, except pallor, were noted in the 78-year-old man with diffuse involvement of the colon. Two of the patients with ascending colon lesions exhibited leukocytosis. All but two of the foregoing patients were anemic. Four patients had had barium enemas carried out with the following diagnoses: diverticulosis, one; carcinoma of the transverse colon, one; polyp of the cecum, one; ileocecal intussusception, one. Thirty-eight of the 62 patients with sigmoid diverticulitis exhibited lower abdominal tenderness, most marked in the left lower quadrant. In 19 patients a mass was palpable. Fifteen patients exhibited varying degrees of distention. Six were febrile on admission. One patient developed an abdominal wall fecal fistula shortly after admission. Two patients had such fistulas at the time of admission and in one of these patients it was associated with a clostridial wound infection. Two patients had colonic stomas when first seen. In 13 patients no abnormal physical findings were reported.

In 21 of these patients varying degrees of anemia were present, and 31 had elevated leukocyte counts on admission. Proctoscopic examination was carried out in 25 patients, with positive findings in 13. In three patients this consisted only of the presence of blood coming from the upper reaches of the intestine, whereas in the remainder evidence of inflammation and occasionally the presence of diverticula were noted. A plain film of the abdomen was made in 10 patients with the following diagnoses: abdominal mass, 1; intestinal obstruction, 5; negative, 4. A barium enema was carried out in 46 patients with the following diagnoses: diverticulitis, 27; diverticulosis, 10; carcinoma, 3; constricting lesion, 3; extrinsic tumor, 2; and negative, 1. In two of the patients in whom radiologic diagnosis of diverticulitis was made, the possibility of a carcinoma could not be excluded. Among the 11 patients in whom the diagnosis was "diverticulosis" or "negative," 8 were found at operation to have severe, active diverticulitis.

We were interested in learning what the clinician thought he was dealing with before the patient was operated on and also in the accuracy of the surgeon's assessment of the findings at operation. Preoperative diagnoses are shown in table 1. No correct ones were made in patients having lesions of the cecum or transverse colon. Although the condition was known to exist throughout the entire colon in the patient ultimately undergoing colectomy, the source of the bleeding was incorrectly inferred and a hemorrhoidectomy carried out first. Among patients with sigmoid lesions a correct diagnosis was made or strongly suspected in 61%. One of the patients on whom a correct preoperative diagnosis was made here entered the hospital with a fecal fistula and a clostridial wound infection resulting from an operation carried out elsewhere on what was thought to be a strangulated inguinal hernia, six days previously.

Table 1.—*Preoperative Diagnosis in Seventy Patients with Diverticulitis*

Location of Lesion	Diagnosis	No.	% Correct
Cecum	Acute appendicitis	3	0
	Carcinoma	2	0
Transverse colon	Strangulated periumbilical hernia	1	0
	Carcinoma	1	0
Entire colon ..	Diverticulitis	1	100
Sigmoid colon	Diverticulitis	29	61
	Possible diverticulitis	9	
	Carcinoma	7	
	Gynecologic disease (ovary 6, uterus 1)	7	
	Acute appendicitis	5	
	Unknown or incidental finding	5	

At the time of operation the correct pathology was recognized by the surgeon in three patients with cecal lesions; in two he thought he was dealing with a carcinoma. The true nature of the condition was apparent in the patients having lesions of the transverse colon and entire colon. Among the patients with sigmoid lesions a correct assessment was achieved in 85%. In four patients the lesion was thought to be carcinoma, while in five the surgeon was uncertain as to the nature of the lesion with which he was dealing.

Treatment

Operative procedures which were performed are indicated in table 2. Among the patients with cecal lesions, right hemicolectomy was carried out in two patients because the lesion was thought to be malignant and in the third because of the extent of the process. Local procedures were utilized when the inflammatory nature of the process was obvious and circumscribed. In both patients with transverse colon lesions, the inflammatory nature was obvious and the extent of the process dictated whether resection or excision was performed. The patient with extensive involvement of the entire colon underwent subtotal colectomy after an ill-advised hemorrhoidectomy failed to curtail his bleeding.

Sigmoid diverticulitis was treated by primary resection and anastomosis in 35 patients. None of these patients had complementary cecostomy or colostomy performed. In only eight patients was the pathological process quiescent at time of operation. In 20 patients marked inflammatory activity was present and 2 of these patients were partially obstructed. In six seriously ill patients abscesses were encountered, and in one patient acute perforation with generalized peritonitis was present.

Stage procedures were carried out in 14 patients. In one instance complementary colostomy was established because of an uncertain anastomosis. In two instances the presence of a large abscess and in one the presence of a clostridial wound infection were the reasons for stage procedures; two of these patients had associated fistulas, as did one other patient in whom a stage procedure was carried out. In five patients the presence of obstruction in a poor-risk patient with active disease was the indication for preliminary decompression. In three instances the true nature of the process was wholly unsuspected, no preparation for an intestinal operation had been carried out, and it was felt unwise to proceed with a primary resection; two of these patients were operated on with a diagnosis of "acute abdomen" and the third because of a mass. The final patient had a ruptured diverticulum, generalized peritonitis, and a gallstone impacted in the terminal ileum.

In four patients local procedures were carried out: in one instance this was done in association with a salpingo-oophorectomy in an effort to relieve low-grade obstruction; in one, after appendectomy, to remove a piece of bone protruding from a perforated sigmoid diverticulum. It was hard to explain the surgeon's choice in the other two patients, in both of whom diverticula were removed, once because of acute perforation and once in association with colporrhaphy and hysterectomy.

Transverse colostomy was performed twice, once in an 87-year-old man with perforation and peritonitis, and once in a 75-year-old critically ill man with severe cardiovascular disease who had obstruction due to his diverticulitis and hemoperitoneum from a bleeding hemangioma of the liver. In the remaining seven patients with sigmoid diverticulitis, although the process was recognized at operation, no procedure conducted directly against it was carried out. In two instances pus was encountered and drainage instituted. Four times diverticulitis was discovered in the course of other operative procedures and because of lack of preparation or history of adequate medical care, a conservative course was elected. In one case when coloscopy failed to reveal the source of bleeding from the intestine, the abdomen was closed and the patient's hemorrhoids removed.

Table 2.—*Surgical Treatment of Diverticulitis in Seventy Patients*

Segment of Colon Involved	Operative Procedure	No. of Patients
Cecum	Right hemicolectomy	3
	Excision and appendectomy	2
Transverse colon	Resection transverse colon	1
	Local excision	1
Entire colon	Subtotal colectomy	1
Sigmoid colon	One-stage resection	35
	Multiple-stage resection	14
	Local procedure	4
	Colostomy only	2
	Exploration	7

In all cases in which tissue was removed the pathologist confirmed the diagnosis of diverticulosis or diverticulitis. In one patient a 3 mm. sessile polyp also was found to be present, and in another a grade 2, Duke's A adenocarcinoma 1 cm. in diameter was found to be present in the removed sigmoid segment.

Postoperative Course

The postoperative morbidity and mortality are given in table 3. One of the five patients with diverticulitis of the cecum developed mild femoral thrombophlebitis, and one developed a large wound hematoma. The convalescence of the remaining three was uneventful. Both patients operated on for diverticulitis of the transverse colon had an uneventful convalescence. The patient who was operated on for diverticulitis of the entire colon developed an infected wound hematoma and a severe transfusion reaction complicated by jaundice. Among the 35 patients undergoing one-stage resection for diverticulitis of the sigmoid, complications occurred in 7. In one instance the left ureter was injured in the process of mobilizing the acutely inflamed sigmoid; fortunately, the injury was noted at the time of operation, repaired over a T-tube, and caused no further trouble. One patient went into shock postoperatively. One patient was thought to have developed a leak in the anastomosis; the process responded well to conservative therapy. There was one instance of ileus and one of small intestine obstruction, both of which responded well to conservative measures. One patient developed transient auricular fibrillation. One patient had to be readmitted because of a mild wound dehiscence. A number of patients were troubled with transient diarrhea and weight loss, but in none did this persist or become a serious problem. Transient mental depression and confusion were occasionally noted in the immediate postoperative period.

TABLE 3.—*Morbidity and Mortality Among Seventy Patients Operated on for Diverticulitis*

Segments of Colon Involved	No. of Patients	Patients with Post-operative Complications	Deaths
Cecum	5	2	0
Transverse colon	2	0	0
Entire colon	1	1	0
Sigmoid colon:			
One-stage resection and anastomosis	35	7	0
Multiple-stage and other procedures	27	10	2

Among the 14 patients having stage procedures there was one death. This occurred in a 78-year-old woman on whom a colostomy was performed for acute perforation of a sigmoid diverticulum with generalized peritonitis and in whom an impacted gallstone had to be removed from the ileum at the same time. Three weeks later the diseased segment of the sigmoid was resected. Postoperatively she developed congestive heart failure, the anastomosis leaked, generalized peritonitis developed, and she finally died of a pulmonary embolus on the seventh postoperative day. Complications among the remaining patients included two instances of severe wound infection with abscess formation, one of recurrent fistula, one of small intestine obstruction, one of gangrenous cholecystitis, and one of prolonged urinary retention. Shock followed closure of colostomy in one patient, and another had an unexplained fever for some time. Again diarrhea was occasionally troublesome in the postoperative period. In two of the patients undergoing local procedures recovery was uncomplicated; the course of the other two was febrile, in one associated with the development of a large abscess. Of the two patients on whom transverse colostomy was performed, one, aged 75, died on the 33rd postoperative day of pneumonia which followed atelectasis. The other, aged 87, recovered uneventfully. In those patients in whom nothing was done about the diverticulitis per se at the time of operation no complications occurred, with the exception of one patient who had prolonged urinary retention and syncopal episodes.

Comment

When this clinical study was initiated, we had in mind several questions in regard to the diagnosis and management of diverticulitis, the answers to which we felt were not clear. We do not have a complete answer to each of these questions; nevertheless, we feel justified in presenting certain facts from which, in our opinion, a number of conclusions may be drawn. Diverticulitis, in portions of the colon other than the sigmoid, occurred with such infrequency that it would seem unjustifiable to do more than call attention to the fact that it does occur and is seldom diagnosed before operation.

To discuss the diagnosis of sigmoid diverticulitis might seem elementary, yet we were astonished to find that this diagnosis was not even considered by either clinician or surgeon prior to operation in 39% of the cases we reviewed. An analysis of the reasons for faulty diagnosis brings out the following significant points:

1. Diverticulitis frequently presents a clinical picture mimicking gynecologic disease or carcinoma of the intestine. Others [5] have adequately emphasized concern as to avoiding the pitfall of mistaking sigmoid carcinoma for diverticulitis. To this we heartily lend support, yet in our group of patients no such error was made. Instead, in 14 cases neoplastic disease of the intestine or pelvic organs was the sole preoperation impression, gained, it seems, as the result of a mass being palpable in the lower part of the abdomen or on pelvic examination and in the absence of signs of inflammatory disease. We would urge, as have Bacon and Sherman,[6] the inclusion of sigmoid diverticulitis in the differential diagnosis of such a mass regardless of its size and the absence of local tenderness or systemic evidence of inflammatory disease.

2. In contrast to the above, diverticulitis coli, complicated by perforation, may mimic diseases which produce generalized peritonitis, in particular, appendicitis. Careful clinical examination should help to minimize this mistake, as should keeping in

mind the fact that perforating sigmoid diverticulitis can present abdominal signs elsewhere than the left lower quadrant, as Fallis and Marshall[7] have pointed out.

3. An absence of significant aberration of lower gastrointestinal function should not lead to the exclusion of acute sigmoid diverticulitis from the differential diagnosis. In 18 of our cases (30%) a change in bowel habit had not occurred or was so slight that it seemed insignificant. Colcock[5a] states that 35% of his patients had a change in bowel habit, implying that as many as 65% had no such helpful diagnostic symptom. This is in contrast to Judd and Mears,[8] who report that only 2 out of 68 surgical cases of diverticulitis had no bowel symptoms.

4. Leukocytosis is as frequently absent as it is *present in acute diverticulitis of the sigmoid colon*, according to our study. This surprising finding is another factor urging us to call attention to the frequency of the noninflammatory character of the clinical picture in many patients. Of the 32 patients in our group whose white blood cell count was 10,000 per cubic millimeter or under, many were acutely ill, and, whereas diverticulitis was diagnosed in most, in 12 of this group it was not suspected.

5. Fever was absent as often as present in patients with acute diverticulitis.

6. Bleeding from diverticula or as a symptom of acute diverticulitis coli has received a good deal of attention in the literature. Gross bleeding was noted by 13 of our patients, but was only one symptom among many except in 4 patients in whom it was the sole presenting complaint. Massive hemorrhage was the chief cause for surgery in two of these patients. Certainly gross bleeding should first of all suggest a disease of the intestine other than diverticulitis. When it does arise from diverticula, it frequently makes the diagnosis extremely difficult.

7. A report from the radiologist indicating the presence of diverticulosis of the sigmoid without evidence of diverticulitis does not mean that significant inflammatory changes are absent. This discrepancy should be recognized by all clinicians and is one of the pitfalls of blind belief in the infallibility of x-ray examination. In 11 instances in our group of patients the radiologic report was decidedly misleading.

We have made no comments concerning the type or location of pain suffered by these patients, inasmuch as we were unable to note any pattern of distress that has not been fully discussed elsewhere. Insofar as treatment is concerned this study deals only with patients operated on. The reader is directed elsewhere for a detailed discussion of indications for operation. Among our patients the indications were, in order of frequency: intractability of symptoms, the presence of a palpable mass, the inability of the radiologist to exclude carcinoma, obstruction, bleeding, and external fistula.

Surgical Procedures.—Surgical procedures may well be considered in three catagories: (1) the elective operation, (2) the emergency operation, and (3) the surprise operation.

When operation is carried out as an elective procedure during a quiescent phase of the disease there is general agreement that a one-stage resection and anastomosis is the procedure of choice.[8] Resection can usually be limited to the sigmoid even though diverticula may be scattered throughout other parts of the intestine. In only one of our patients was it necessary to carry out a subtotal colectomy. In the more complicated case there is no such unanimity of feeling. It is our feeling that a phlegmonous process in the intestine wall, with or without miliary abscesses and extensive local adhesions, low grades of obstruction, severe bleeding, *and fistula do not render a multistage procedure* mandatory. It should be the condition of the patient rather than the local findings which influences the decision. If the patient is in good general condition and well prepared, it is usually possible to get above and below the diseased segment to achieve a satisfactory anastomosis of comparatively normal intestine. The more radical procedure is sometimes the safer. By adequate mobilization and resection one removes all diseased tissue, avoids tension on the anastomosis, and eliminates the need for subsequent operations with their attendant risks, time loss, and expense. This was the policy followed in 35 of the 62 patients having sigmoid diverticulitis and 5 of the 8 patients with diverticulitis in other portions of the colon. There were no deaths in this group; complications were less frequent and for the most part comparatively trivial.

In the presence of high grades of obstruction, when a large abscess is present which cannot be removed without profound soiling of the peritoneal cavity and leaving behind much devitalized tissue, or when the patient's general condition is poor, obviously a staged procedure offers the only safe approach to the problem. A transverse colostomy will usually allow the inflammatory process to quiet down and keep it quiet as long as the stoma is functioning. This alone may be all that can be done in an extremely poor-risk patient and may offer excellent palliation as far as the diverticulitis is concerned. It is interesting to note that one of our two deaths occurred when a colostomy alone was performed. After recovery from the colostomy, at an interval of two weeks to several months, the diseased segment of intestine may be removed whenever the patient's general condition warrants. If the resection and anastomosis are easily accomplished, many times the colonic stoma may be closed at the same time. If the procedure is difficult, the condition of the intestine leaves much to be desired, and the patient's general condition is poor, closure should be carried out as a third stage. Our only other death occurred in a poor-risk patient in whom multiple severe complications followed a staged procedure. In general, complications were more frequent and severe in this group of patients.

We were surprised to find a few local procedures still being carried out. In the ascending or transverse colon this may occasionally be adequate. In the sigmoid, where multiple diverticula usually exist, it is difficult to justify attempts to remove individual diverticula. Pemberton and co-workers[3] long ago decried the practice as seldom conducive to lasting relief from disease. Similarly, in two cases with localized peritonitis and abscess, drainage alone was carried out. Both patients survived but in neither, of course, was the basic problem solved.

When acute perforation occurs with spreading or generalized peritonitis, the need for emergency operation is unquestioned, but as to procedure the decision may be difficult. Although acute perforation occurred in four of our patients, it is not common. Pemberton and co-workers[3] reported no instances of acute perforation in 389 cases of diverticulitis. Mayo and Blunt,[9] discussing complications of diverticulitis, found abscess in 57 of 202 cases but no free perforation. Fallis and Marshall[7] reported five deaths with conservative treatment of acute perforation. Exteriorization or extraperitoneal resection would seem to be the logical procedure. However, it is seldom feasible as the mesentery is often short and thick and all the affected intestine cannot be safely brought to the outside. In general, closing or patching with omentum of the perforated diverticulum is the procedure of choice, although sometimes only drainage can be carried out. Needless to say, a transverse colostomy always should accompany procedures of this type. Closure or drainage without complementary colostomy offers questionable security.

Since accurate diagnosis at operation is particularly difficult in the presence of acute perforation, subsequent resection should be carried out not only to remove the diseased intestine but also to avoid the disaster of leaving a carcinoma behind. Immediate primary resection and anastomosis may be done if the patient is seen early and conditions are favorable. Unfortunately, this seldom is the case, but in one of our patients it was done with an eminently satisfactory result.

The surprise operation is performed with distressing frequency. This situation prevails when the first intimation of the correct diagnosis is obtained after the abdomen is opened. Because of lack of proper conception of the problem, the usual routine preparations which have added so much to the safety of elective intestinal surgery have not been carried out. The actual operation finds both the surgeon and the patient unprepared for what should be done. Sometimes, as in the presence of perforation, abscess, or obstruction, the surgeon has no alternative but to proceed boldly and hope for the best. However, in the presence of uncomplicated diverticulitis, be it fulminating or quiescent, a dilemma may present itself. In seven patients in our series the surgeon elected to correct any associated lesions and back out, planning to give the patient a trial of adequate medical therapy and then, if necessary, to reoperate and resect the diseased intestine under more favorable circumstances. However, in most cases where the disease was pronounced, the surgeon faced his problem resolutely and attempted some type of definitive procedure. One can only hope that periodic references to this disease in the literature will serve as a reminder of the frequency of its occurrence and keep "surprises" at a minimum.

Summary

Diverticulitis of the colon is a common condition frequently necessitating surgical treatment. It must be considered in the differential diagnosis of intra-abdominal disease, especially if an abdominal or pelvic mass is present, regardless of the absence of localized or generalized signs of inflammation and regardless of an x-ray report of diverticulosis instead of diverticulitis. In an increasing number of patients the surgical treatment of choice is one-stage resection and anastomosis. In the present series of 70 patients this was carried out in 57% of the total patients with diverticulitis and in 71% of the patients with sigmoid diverticulitis undergoing definitive surgery, with no deaths and minimal morbidity. No longer should this procedure be reserved merely for the uncomplicated or quiescent cases. If recognition and treatment are delayed until serious complications develop, multiple-stage procedures may still have to be carried out.

SURGICAL MANAGEMENT OF ULCERATIVE COLITIS

Rupert B. Turnbull Jr., M.D., Cleveland

Surgical treatment becomes necessary in a certain number of patients with ulcerative colitis who do not respond to medical management. The operation of low ileorectal anastomosis here described is done a year or more after subtotal colectomy and ileostomy. It consists in mobilizing the rectum, excising part of the rectum with the sigmoid colon, and making an end-to-side anastomosis of ileum to the remaining part of the rectum. During the first few weeks after the second stage, frequent defecations caused considerable disability, but this generally subsided. In 13 patients rectal continence was attained after the first several defecations after the ileoproctostomy; in the remaining one patient incontinence persisted because the sphincter had been damaged by years of preoperative disease. In all cases the anastomosis healed without formation of abscess or fistula. This operation should be considered whenever the rectum and its sphincter mechanism have escaped serious damage, since it offers the hope of avoiding a permanent ileostomy.

The medical management of chronic nonspecific ulcerative colitis is the province of the gastroenterologist. The judicious use of steroid therapy, blood transfusions, certain sulfonamides, and diet under hospital supervision has resulted in satisfactory arrest of the disease in 80% of patients with ulcerative colitis. Surgical management is reserved for those who do not respond to medical therapy. In past years the incalculable morbidity attending the surgical treatment of this disease has led gastroenterologists to defer surgery and to prolong medical treatment despite hopeless odds. This rigid attitude is now being softened by a marked reduction in morbidity that may be attributed to the practice of two principles: "removal of the disease" and construction of a physiological ileostomy.

The absolute indications for immediate surgery are (1) massive uncontrollable hemorrhage, (2) fulminating and diffuse toxic ulcerative colitis, with distention of the colon, (3) perforation with peritonitis, and (4) carcinoma arising in the course of the disease. Elective or probable indications for surgery are (1) unremitting diffuse disease of two or more years' duration, (2) repeated intestinal hemorrhage and persistent anemia or both, (3) diffuse, uncontrollable skin disease (pyodermas), (4) progressive deforming rheumatoid arthritis or spondylitis, (5) ocular disease (iritis, keratoconjunctivitis), and (6) uncontrolled disabling anorectal disease (fistulas, suppurative fissures, abscesses) leading to incontinence. In addition, certain surgical indications are contingent on progression of the disease, such as neurological manifestations like peripheral neuritis or cases of intractable disease in which the patient fails to maintain a satisfactory economic status.

The surgical treatment of ulcerative colitis has been greatly improved and simplified in the last decade. Surgeons now recognize that to effect a "cure" all of the diseased intestine must be removed and that morbidity is lowest for the one-stage colectomy as compared with the older multiple-stage procedures. The lower mortality of colectomy and simultaneous ileostomy in the critically ill patient and in the patient with toxemia, as compared with that of a diverting ileac stoma, is appreciated.

Colectomy is now performed through an incision in the left side of the abdomen, leaving the right side free for the ileostomy and the immediate application of soft, transparent, plastic bags for skin protection (fig. 1). Conventional ileostomy has largely been abandoned in favor of some form of eversion technique [1] with primary suture to the skin, which has resulted in normal small intestinal function within a few days after colectomy. This technique has eliminated the fluid and electrolyte problems and the nutritional failure previously observed during the postoperative period. The rapid return to health and vigor has made the ileostomy more acceptable to the patient, and the development of a variety of ingenious ileostomy appliances and skill in fitting them has done away with much of the danger of corroding the skin.

New Concept—Ileorectal Anastomosis

The practice of one-stage "removal of the disease" has led some surgeons to extirpate the colon and rectum at one operation. This eliminates forever the possibility of restoring intestinal continuity. In 1956, Aylett [2] reported his experiences with ileorectal anastomosis after colectomy. He pointed out that the success of the procedure depended on the removal of not only the colon but also the rectosigmoid. He further stated that after low ileorectal anastomosis the diseased rectal segment healed.

From the Department of General Surgery, The Cleveland Clinic Foundation, and The Frank E. Bunts Educational Institute.

Read before the Section on Gastroenterology and Proctology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Follow-up serial biopsy studies revealed mucosal surface healing, although restitution to integrity of the basic architecture of the submucosa could not be expected if it had been scarred by the disease. He presented clinical evidence to show that the lower part of the rectum would not only recover from active disease, but would function adequately as a terminus for the small intestine.

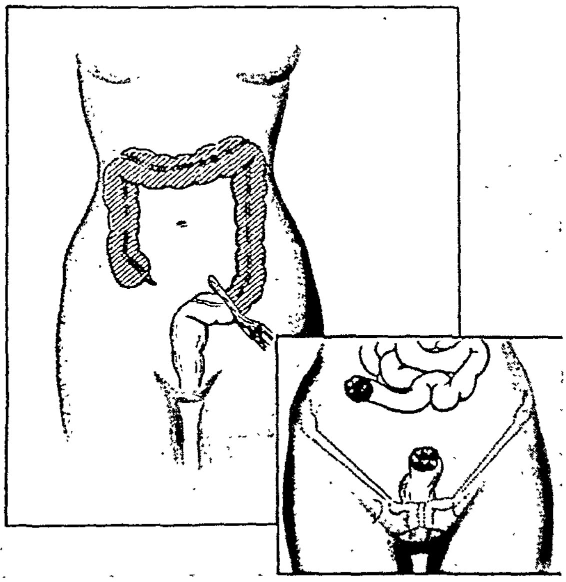

Fig. 1.—First stage of subtotal colectomy and ileostomy.

Aylett's interest in the possibility of ileorectal anastomosis was aroused by his clinical observation that the majority of patients with the diffuse form of the disease had minimal gross involvement of the ampulla of the rectum, while the area immediately above (rectosigmoid and sigmoid colon) was most ulcerated and deformed; e. g., pseudopolyps are often seen first at the rectosigmoid. He postulated that the rectum was least diseased because of its separate nerve supply and that it was kept inflamed by "drip-down" from the suppurative lesions above. Resection of the colon and the rectum down to a point below the deforming disease (about 4 in. above the anus) and mobilization of the lower part of the rectum from the presacral space not only would remove the gross deforming disease but would denervate most of the ampulla as well. Aylett[3a] has had excellent results in 100 patients with diffuse ulcerative colitis who have undergone colectomy with ileorectal anastomoses. His operative technique[3b] has been described in detail. He utilizes a two-stage procedure with a temporary ileostomy above the ileorectal anastomosis.

Since June, 1957, I have performed low ileorectal anastomoses in 14 patients having diffuse ulcerative colitis. The surgical technique differs from Aylett's in that (1) ileorectal anastomosis is done a year or more after subtotal colectomy and ileostomy, and (2) no decompressive ileostomy is done at the time of ileorectal anastomosis. The results so far have been satisfactory, although the number of patients is small and the observation period is short. More time and experience will be necessary for final evaluation, but it appears that the operation has a distinct place in the surgical treatment of this disease.

Technique.—Mobilization and resection of the rectum and sigmoid colon and low ileorectal anastomosis constitute the principal surgical maneuvers. Mobilization of the rectum involves the following procedures: The presacral space is entered medial to the left ureter and in front of Waldeyer's fascia. Sympathetic nerve trunks are preserved on either side. The peritoneal folds at the base of the mesorectum are incised part way down toward the rectovesical pouch or cul-de-sac, and the rectum is brought forward and upward from the sacrum by blunt dissection down to the tip of the coccyx. The middle hemorrhoidal vessels are not divided. The anterior peritoneal reflection is thus elevated to a comfortable position where the rectum may be cut across about 2 in. above it, and end-to-side anastomosis with the ileum is made (fig. 2). Important details in the technique are (1) dilatation of the open end of the divided rec-

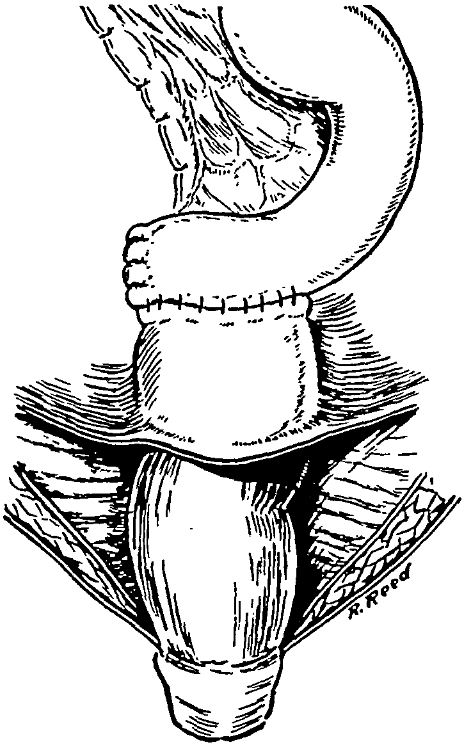

Fig. 2.—Second stage of resection of sigmoid colon and upper part of the rectum (ileoproctostomy).

tum if it is contracted; (2) for the anastomosis, the use of interrupted fine catgut sutures through all layers, and an outside seromuscular approximation with silk: interrupted sutures to avoid stenosis, and absorbable catgut to avoid through-and-through fistulas in the presence of active rectal disease; (3) the pelvis should not be reperitonealized, to allow accumulated blood to drain up into the abdominal cavity rather than to be confined at the anastomosis; and (4) the ovaries in premenopausal women should be sutured with silk to the round ligaments so that they will not prolapse into the presacral space where they may become extraperitonealized and cystic.

Early Results.—The primary disability after ileoproctostomy consists of multiple daily bowel movements which decrease within the first few weeks. The ileum above the anastomosis gradually dilates, as does the rectal ampulla. It is my opinion that more of the terminal ileum, if not diseased, could be saved at the time of colectomy, which would make possible a more solid bowel movement. Six of the patients in this series take antidiarrhea medication.

Aylett [3b] reports no recurrence of proctitis. We have not been so fortunate, although rectal disease present at the time of anastomosis has healed in all but three patients who had persistent disease of the rectum and suppurative cryptitis from three to six months after ileorectal anastomosis. Rectal continence has been well preserved except in the case of one patient who many years previously had sphincter damage and anal fistulas and now wears a pad for occasional leakage. Ileostomy has been reestablished for this reason. In all 14 patients incontinence of the rectum has occurred only for the first several movements after ileoproctostomy.

Sporadic reports of colectomy and ileoproctostomy have been published,[4] but from these accounts we cannot be sure at what level in the rectum the anastomosis has been made. This is most important, since according to Aylett [3] the retention of the involved pelvic colon or rectosigmoid is the principal cause of failure. To clarify this point, I would define the rectum as being 5 in. (15 cm.) in length above the dentate line. Ileorectal anastomosis is made below this level which, viewed within the abdomen at the time of surgery, would be 5 cm. or less above the peritoneal reflection (fig. 2). The lower level of resection would depend on the level of deforming disease, as it must be made below it.

With regard to the healing of the anastomosis between the diseased rectum and the normal ileum, although there was grossly recognizable ulcerative disease at the site of the rectal section all anastomoses performed on patients in this series have healed without formation of abscess or fistula. Care was taken not to spill intestinal contents, and each sigmoid colon was injected with a large volume of 1% neomycin sulfate solution prior to section and anastomosis. An indwelling rectal tube drained any accumulation of pus or stool during the mobilization period. Although the possibility of the development of cancer in the retained rectum must be conceded, I believe it is extremely unlikely since mucosal healing occurs after ileorectal anastomosis.

Failure of Ileoproctostomy.—Of 14 patients in whom ileoproctostomy was done there have been 4 who must be classed as clinical failures. In two the rectal disease has failed to heal. These patients are in moderately poor health and are disabled by frequent small bowel movements. The disease has not become worse nor is the adjacent ileum involved. Both refuse ileostomy. One other patient has already been mentioned as lacking sphincter control. Constant soiling of his perineum resulted in an uncontrolled dermatitis with pruritus, and he was relieved by reestablishment of the ileostomy. The fourth patient, a 15-year-old girl, had previously undergone subtotal colectomy and ileostomy. Much of the terminal ileum was found to be involved with ileitis; nevertheless, ileorectal anastomosis was done about a year later. Persistent ileitis has responded to medical management.

Conclusions

The indications for surgical treatment of ulcerative colitis are unchanged. The postoperative recovery period has been greatly shortened by the use of one-stage procedures and the construction of a physiological ileac stoma. Of the newer surgical concepts, the restoration of intestinal continuity by low ileorectal anastomosis is of particular interest. The results in the 14 cases herein reported indicate that there is a place for this procedure in the surgical treatment of this disease. With hope in sight for the avoidance of permanent ileostomy, the heretofore common practice of total proctocolectomy should be supplanted by subtotal colectomy, whenever the rectum and its sphincter mechanism have not been severely damaged by the disease.

2020 E. 93rd St. (6).

ORGANIZATION AND OPERATION OF A POISON CONTROL CENTER

T. George Bidder, M.D., William W. Herman, M.D.
and
Irving Sunshine, Ph.D., Cleveland

To establish a poison control center means to create an agency that can communicate to a physician, under emergency conditions, the chemical composition of ingested substances and suggestions for diagnosis and treatment. The most important requisite for successful operation is a properly qualified professional person who, by reason of being compensated for his efforts, can devote a sufficient amount of time and energy to the program. Salaries therefore represent the largest items in the budget. Systematic use of the telephone as here described enables the center to function on a 24-hour basis, although at the Cleveland center 97% of the calls have come in between 8 a.m. and midnight. In addition to directly saving lives, the center has done much by means of education to prevent poisonings and serves as an excellent vehicle for improving public relations.

The statistics on accidental poisoning in the United States are grim. Probably close to a quarter of a million children under the age of 5 years ingest toxic or potentially toxic substances each year. Of these, about 300 to 400 will die. Two factors can reduce both of these figures—prevention and prompt, effective treatment. In recognition of this, the physicians of many communities have established poison control centers. It is probable that most communities will, in the near future, want to organize such a center to deal with their problems of accidental poisoning.

In the past five years physicians, and pediatricians in particular, have become acutely aware that accidental poisoning is an important, frequent, and serious problem. A major facet of this problem has been the fact that a great many household products sold to the American public do not give information on their ingredients, toxicity, or effective antidotes. This information is essential to the physician who has to treat cases of accidental poisoning involving these products. With more than a quarter of a million household items being sold and the number rapidly increasing each year, it is clear that the American youngster has potential exposure to substances that may lead to poisoning accidents.

We have, for the past two years, been concerned with the establishment and operation of a poison control center in a large metropolitan community. Previous to that we provided, over an eight-year period, information on poisoning to the medical community under a less formal and organized arrangement.

It appears desirable to record our experiences for several reasons, the most important being the fact that the fundamental principles underlying the establishment of a poison control center and its successful operation do not differ greatly whether the community is small or large. For the most economical use of energy and funds which become available for the establishment and maintenance of a poison control center, it is essential to know what has already been done and what is available and therefore need not be created *de novo* by each center.

Organization of a Poison Control Center

In June, 1957, the Academy of Medicine of Cleveland, with the aid of a grant from the Cleveland Foundation, started a poison control center. The establishment of a poison control center involves the creation of an agency or mechanism by virtue of which the physician, encountering a poisoning accident, can be "plugged-in" to the latest and most authoritative sources of information on the chemical composition of the ingested substances and on diagnosis and therapy.

There are now nearly 200 centers in the United States, and more are being formed. They do not all perform the same service. Some are information-dispensing agencies, others treat victims of poisoning accidents in addition, and a few have a still more complex organization and send trained personnel to follow up each accident with a home visit. Home visits produce data about the accidents which can be, and in some cases are, used to educate the rest of the community as to the nature of the hazard and possible steps that can be taken to avoid or minimize its recurrence.

The Cleveland center, in the first 15 months of its existence, has averaged 8-12 calls per day. Of these calls, 77% are from lay persons. Fifty-two per cent of the calls come between 8 a. m. and 4 p. m. and 3% between midnight and 8 a. m. Of the annual calls, 973 (31%) have involved medicaments, 603 (19%) household products, and 542 (17%) cleaning agents.

From the Poison Control Center, Cleveland Academy of Medicine.

The most important factor determining the successful operation of any poison control center is the acquisition of a properly qualified professional person or persons who can devote a sufficient amount of time and energy to ensure the proper functioning and continuity of the program. We feel that the only way to acquire this time in a reliable and continuing fashion is to pay for it. It is true, and undoubtedly will remain true, that some communities will be blessed with interested persons who will devote the requisite amount of time, for a short period, without remuneration. However, it is our belief that the great majority of communities wishing to establish a poison control center, however small, will not be so fortunate. We would recommend that the primary use of money available for the establishment of a center should be the remuneration of a professional person who will regularly and continuingly devote a definite amount of time to the direction of the center. In the Cleveland experiment, one of the first steps was to secure the services of a medical director and a technical director. Their salaries, and that of a part-time secretary, represent the largest items in the financial aid requested and received for this project.

Duties of a Director.—In small communities, the director may be the embodiment of the center—he will take all calls, will be the repository for the stores of information available, and, perhaps, will act as a consultant in cases of poisoning. In most instances, however, he can be far more effective if his time is spent in organizing and controlling the various facilities needed to operate the center, assembling sources of information, and keeping them up to date. In addition, the director can initiate and supervise programs designed to educate physicians in the proper management of poisoning cases and to acquaint lay persons with the hazards and prevention of accidental poisoning and with the proper utilization of facilities available for the treatment of such cases. The following description of these duties is based on the program at the Cleveland center.

The technical director, a chemist and toxicologist, was appointed to organize material on the vast number of chemical substances included in the formulations of products involved in poisoning. Under his direction, a comprehensive library of books and pamphlets was assembled and kept up to date to provide specific as well as general information about the chemical composition of individual products as information was obtained from many different sources. Community resources were utilized to obtain consultants in various specialty fields, such as botanicals, economic poisons, protective coatings, and industrial chemicals. All these persons are on 24-hour call. If local resources are inadequate, the telephone brings any area of the United States within relatively easy reach for prompt resolution of a special problem.

A medical director, an internist, was appointed to deal with the problems of therapy and with clinical aspects of poisoning. In addition, a group of physicians with highly specialized interests is available for consultation.

Facilities.—Poisoning accidents are emergencies which may arise at any time and which require immediate attention. At this center, dialing a well-advertised telephone number connects the caller with the operator at the Academy of Medicine's 24-hour call service. This operator will, through a direct line to the University Hospitals, contact the resident physician on call for poisoning cases. At this hospital, members of the senior resident staff of the pediatrics service rotate through the duties of poison control officer as an integral part of their training. In every case the operator gets the name, telephone number, and agent involved and ascertains whether the patient's private physician has been called. This information is taken while the operator is awaiting the poison control officer's answer. Every effort is made to have the patient contact his private physician, and his call is put through to the poison control officer only when the private physician cannot be located or in cases in which urgency is apparent or in cases in which the caller has no private physician. An advantage of routing all calls through the Academy of Medicine telephone service is that these operators are skilled in locating physicians and can be doing this while the patient is speaking with the poison control officer or is on his way to a hospital emergency room.

The sole function of the poison control officer is that of supplying information. To this end, a complete library of books, pamphlets, and memorandums on poisoning is kept in one or more strategic locations in the hospital. A list of these books has been published.[1] At the Cleveland center, the poison control officer has other hospital duties which keep him in the vicinity of a telephone in an outpatient department office during the day. This telephone is a special line, used only for calls on poisoning, so that there will be no hold-up due to busy hospital lines. The major, and most complete, library of information is kept in this outpatient department office, since the vast majority of calls come during the day. After 4 p. m. the poison control officer is either at Babies and Childrens Hospital, where he can readily use the main library, or else he is in the hospital emergency room or in his living quarters. Duplicates of the most useful sources of information have been placed in each of the latter two places. If the poison control officer is not near the special telephone, the Academy of Medicine's call service operator can call the University Hospitals on a private trunk line that eliminates delays. From the hospital, where a Telepage call system is used, the poison control officer is called as "Doctor Pico" (abbreviation for poison information center officer). By using this system, the operator need not know the name of the current poison control officer. Furthermore, should the latter not respond to his call other physicians will call in and take over.

Cuyahoga County covers a large metropolitan area of northeastern Ohio. Physically it was not practical and professionally it was undesirable to have one center in this area. However, the problem of prompt, effective treatment of poisoning accidents is a real one. Recognizing this need, the Academy of Medicine center urged the respective staffs of the local hospitals to create treatment centers at their hospitals. These treatment centers are under the supervision of a visiting physician and are primarily designed for therapeutic activities. Nineteen local hospitals instituted this program, generally under the aegis of a pediatrician. Periodic meetings have been held by this group and the professional staff of the center to discuss mutual problems and recent advances. A protocol for treating a poisoning emergency was drawn up by this group and made an integral part of the respective hospital's procedure. A poison therapy cart has also been described.[1] At a recent meeting it was suggested that another visiting physician be added to the treatment center's staff at each hospital so that an internist and a pediatrician would be available for consultation. Each visiting physician, in addition to consulting with the resident staff on specific problems as they occur, arranges periodic staff meetings to discuss the many problems attendant on proper and effective therapy for victims of accidental poisoning. These meetings generally center about a recent particular local poisoning case and serve to educate the house and visiting staff.

Consultants and Special Facilities.—The efficacy of the poison control center can be significantly increased by use of the technical resources of the community it serves. Thus, it would be well to know the nearest location of an artificial kidney and of a laboratory wherein chemical analyses of body fluids can be done on an emergency basis. In the industries, schools, museums, and health departments of a community, persons can be found who will willingly serve, on a 24-hour basis, as helpful consultants on the identification of botanicals, paints, cleaners, medicaments, and industrial and agricultural chemicals. Such a group of consultants has been invaluable in the operation of this center.

Educational Activities

The circumstances surrounding poisoning accidents are strikingly similar and are such as to convince one that a program designed to educate those who supervise the activities of children under 5 years of age would return a handsome dividend in lives saved and illness prevented. Such a program involves the continuing and repetitive education of medical people, such as physicians and nurses, as well as of nonmedical persons, such as parents, baby sitters, firemen, and policemen. The outline of the educational program sponsored by the Cleveland center, given below, is a guide to what can be done. It should be apparent that this venture consumes time, money, and energy and may well be beyond the immediate objective possible for any such poison control center unless cooperative and collaborative efforts can supply the center with educational material so essential for an educational program.

Education of Physicians.—The following items are included in the educational program for medical people: 1. Lectures, conferences, and clinical-pathological exercises are designed to bring out the problem of poisoning, its diagnosis, its pathological physiology, and its therapy. 2. Articles on poisoning, published in a journal having wide circulation among the local practitioners, are used. The Cleveland center has published articles on the general aspects of poisoning and its therapy and on specific poisonings (salicylate, lead) in *The Bulletin of the Cleveland Academy of Medicine.* The National Clearinghouse for Poison Control Centers puts out an excellent monthly bulletin on the various aspects of poisoning which is distributed to local physicians in charge of treatment centers. 3. Meetings between the professional staff of the center and the physicians representing the local hospitals provide a great deal of mutual education in the way of new therapies, pertinent publications, and interesting cases encountered. 4. Reprints and abstracts of pertinent articles are prepared at the center and distributed to the participating hospitals and, through the latter, to any interested physician. 5. Some pharmaceutical firms publish excellent brochures on the various aspects of poisoning; these are obtained by the center and distributed locally.

Education of Nonmedical People.—Education of nonmedical people involves the following procedures: 1. The physician has an important role in educating the public to the prevention and proper treatment of poisoning. He can place literature in his waiting room. He has the unparalleled opportunity repetitively to bring up the topic of prevention of poisoning accidents to patients who care for small children. When prescribing medicaments, he can stress proper safeguarding and disposal when the drug is no longer needed. By being willing to lecture on this topic to the Parent-Teachers Association and similar groups, he can reach a much larger audience. 2. Pamphlets can be distributed through physicians' offices, pharmacies, visiting nurses, and well-child clinics. A folded, 8-by-11-in., red, black, and white pamphlet on the danger of household preparations was designed at this center. Its theme was "out of sight, out of reach helps keep your child out of trouble." More than 100,000 of these pamphlets have been requested in the past two months. 3. The Cleveland center helped organize and sponsor a poster contest for school children, in cooperation with the Cleveland Board of Education and the Catholic Board of Education. The

Causes of Death in Immature Infants.—The principal cause of death in immature infants was premature rupture of the membranes. Premature rupture of membranes has generally not been listed as an important item in perinatal mortality. A recent study in the three teaching institutions in North Carolina indicated that 15.8% of all deliveries were complicated by this condition while 26.7% of all perinatal deaths were associated with premature rupture of membranes.[4] Believing this complication to be of significance, preference was given to it when there were no other obvious causes of death. Toxemia of pregnancy was an important factor in the deaths of 15.4% of these small infants. Premature separation of the placenta as well as rupture of the marginal sinus accounted for 12.8% of the deaths. Birth injuries, generally associated with anoxia, accounted for 7.7% of these deaths in immature infants.

Socioeconomic Aspects

Recent studies have indicated the importance of parental, fetal, and environmental factors in perinatal mortality.[5] These same factors were found to be important in this material.

Table 3 shows the perinatal mortality in the North Carolina Memorial Hospital according to race and admission status. The perinatal mortality of all deliveries was 48.8 per 1,000 births; for premature and mature infants it was 34.5. When one compares the mortality among the staff patients with that in private patients and similarly for nonwhite and white patients, it is evident that the majority of the deaths were among staff and nonwhite infants. This is even more apparent when the perinatal mortality for the nonregistered group is reviewed. The nonregistered patients were generally indigent white and nonwhite mothers referred from rural hospitals and clinics. The mortality of these immature unregistered infants was 294.9 per 1,000 births, while the death rate for the premature and mature infants was 160.3. When the unregistered group is eliminated from the data, the perinatal mortality in the registered staff and private group approaches a reasonable and acceptable rate of 27.2 and 23.3, respectively, per 1,000 births.

TABLE 3.—*Perinatal Mortality at North Carolina Memorial Hospital According to Race and Admission Status*

Status	Deliveries, No.	Perinatal Mortality per 1,000 Births: 400 Gm. and Above (Total)	Perinatal Mortality per 1,000 Births: 1,000 Gm. and Above
All deliveries	2,728	48.75	34.45
Staff deliveries	1,737	61.02	39.14
Private deliveries	991	27.24	26.23
White	1,816	33.31	27.53
Nonwhite	912	77.85	48.24
Nonregistered*	156	294.87	160.25
Staff-registered	1,581	37.95	27.19
Private-registered	987	23.27	23.27
Total registered	2,568	32.32	25.70
Total	2,728	48.75	34.45

* No prenatal care at North Carolina Memorial Hospital.

There is a striking contrast between the causes of death in private patients and unregistered patients. Malformations accounted for 25.9% of the infant deaths among private patients, while there were no deaths from this cause among nonregistered patients. Toxemia of pregnancy was the principal cause of death in 7.4% of the private patients but 37.5% and 27.3% of the nonregistered group. Premature rupture of membranes did not contribute to a single death in the private patient group, but it was a major factor in the death of 8.3% of the premature and mature infants and 27.3% of the immature infants among nonregistered patients. When major obstetric complications do not occur in a group of patients, there will be an increase in the percentage of nonpreventable causes of death, such as congenital malformations and erythroblastosis.

TABLE 4.—*Cause of Death Among Private and Unregistered* Patients Delivered at North Carolina Memorial Hospital, 1952-1958*

Cause of Death	All Private Patients No.	All Private Patients %	Unregistered Patients: 1,000 Gm. and Above No.	Unregistered Patients: 1,000 Gm. and Above %	Unregistered Patients: Under 1,000 Gm. No.	Unregistered Patients: Under 1,000 Gm. %
Placenta previa	3	11.1	0	0	0	0

Total	27	100.0	24	100.0	22	100.0

* No prenatal care at North Carolina Memorial Hospital.
† Poliomyelitis.

Table 4 compares causes of death in the private and unregistered groups. *Perinatal mortality due to* premature rupture of membranes is clearly a complication among nonwhite staff patients; it was associated with 25.6% of the perinatal deaths. When premature rupture of membranes occurs among infants weighing over 2,000 Gm. (4½ lb.) in the white private patients, it is of minor importance; but when this complication occurs in lower socioeconomic groups, both white and nonwhite, it is a particularly lethal complication.[4]

Table 5 shows data on toxemia of pregnancy and premature separation of the placenta and rupture of the marginal sinus in regard to status of the patient. Toxemia of pregnancy is also seen to be a complication among nonwhite staff patients. Thirty per cent of all deliveries on the obstetric service are nonwhite, but 70% of the cases of toxemia of pregnancy occurred in this group. Moreover, 93.3% of the cases of toxemia occurred among staff patients, but only 6.7% of the cases occurred among private patients. It is important to note that 22.6% of all of the infant deaths were associated with toxemia of pregnancy.

Premature separation of the placenta and rupture of the marginal sinus also were related to the socioeconomic status of patients. Of the total of these hemorrhagic complications, 55.6% occurred in nonwhite mothers, while only 30% of the deliveries were in this group. Of the total cases of premature separation of the placenta or marginal sinus rupture, 77.8% occurred in staff patients, while 22.2% occurred in private patients. Of all the perinatal deaths, 13.5% were associated with this complication.

TABLE 5.—*Analysis of Premature Rupture of Membranes and Toxemia of Pregnancy as Causes of Perinatal Deaths*

	Premature Rupture of Membranes*		Toxemia of Pregnancy†	
	No.	%	No.	%

Not febrile	22	64.7	..	...

* 25.6% of all with premature rupture of membranes.
† 22.6% of all deaths were associated with toxemia of pregnancy.
‡ Associated with fetal distress.

A previous review [5a] of the material in the North Carolina perinatal mortality study revealed that the father's occupation and the mother's education were probably of major importance in fetal and neonatal deaths. The death rates per 1,000 single births of infants weighing 400 Gm. and above, according to three occupation groups of the fathers, are as follows: group 1 (professional people, managers, officials, proprietors, and university students), 29.5 for white infants; group 2 (clerks, sales workers, craftsmen, foremen, and operators), 53.6 for white infants and 46.2 for nonwhite; and group 3 (farmers, farm laborers, other laborers, and household workers), 111.8 for white infants and 82.2 for nonwhite. It is clearly evident that the father's occupation is significant in its relationship to perinatal mortality. Figures for white and nonwhite persons should not be compared, since the occupations of many of the nonwhite fathers were not known and therefore could not be used in the tabulations.

The perinatal deaths, per 1,000 births, in relation to the education of the mother are as follows: among those with more than 12 years of education, 28.0 for white infants; 9-12 years, 65.7 for white infants and 48.9 for nonwhite; and 8 years or less, 70.5 for nonwhite infants. There were insufficient cases for an analysis of nonwhite mothers with more than 12 years of education and white mothers with 8 or less years, but the data available show a distinct correlation with the mother's education and perinatal mortality.

Incidence of Cesarean Section

Eastman [6] has indicated that the incidence of cesarean section in maternity hospitals is between 2 and 6%. There are, however, some private hospitals with a cesarean section rate of over 10%.

The incidence of cesarean section in the North Carolina Memorial Hospital for the five-year period, for a total of 2,700 deliveries, was 58, or 2.15%. However, the incidence among 1,717 staff patients was 27, or 1.57%, and the rate for 983 private patients was 31, or 3.15%. A review of each perinatal death indicated that a more conservative attitude was taken concerning cesarean sections among staff patients than among private patients. There were nine possibly indicated but not performed sections among staff patients but only one section which was possibly indicated but not performed among private patients. Had these 10 patients had abdominal deliveries, the incidence of cesarean section for the service would have been 2.52% and the incidence among staff and private patients would have been 2.09% and 3.25% respectively.

The section rate among staff and private patients should be about equal, with the incidence of the operation being slightly higher among staff patients. It is important to audit at periodic intervals the cesarean sections done on a service so that the incidence of the operation among private patients does not become too high while the incidence of the operation among staff patients does not remain too low.

Possible Errors in Obstetric Management

It is sometimes difficult but always important to analyze all perinatal deaths for possible errors in obstetric and pediatric management. There were 133 perinatal deaths among the 2,728 deliveries between 1952 and 1958. There were 12 deaths (9%) where the obstetric management of the patients while they were in the North Carolina Memorial Hospital possibly could have been improved.

Fetal Distress.—There were five cases of error in the management of fetal distress. Cesarean section probably should have been performed in four of these. Induction was not done in the case of a postmature infant with premature rupture of membranes and the passage of meconium. Concealed hemorrhage was not promptly diagnosed and treated. There was a delay in the diagnosis and treatment of a patient with prolapse of the umbilical cord. Oxytocin (Pitocin) stimulation was continued despite a persistent bradycardia (100 to 110 per minute) in a patient with severe toxemia of pregnancy. Another patient was not properly observed during oxytocin stimulation.

Toxemia of Pregnancy.—The principal errors in the management of patients with toxemia of pregnancy were due to the failure to realize the importance of albuminuria and a reduction in fetal growth. One patient, with severe toxemia, had fetal death in utero when there was an inordinate delay in induction. A second patient had persistent albuminuria and failure of the uterus to increase in size over a four-week period. Fetal death in utero occurred before induction was attempted. A third patient was not promptly admitted to the hospital when severe toxemia developed.

Diabetes.—The major causes of perinatal deaths in pregnant diabetic women in the North Carolina Memorial Hospital has been a failure of referring physicians to provide proper prenatal care and a failure of the patients to cooperate in the obstetric and medical management of their diabetes. There was no correlation between the perinatal mortality among pregnant diabetic women in this hospital and White's classification of such patients[7]; the death rates were a function of the intelligence and socioeconomic status of the mother. Cesarean sections, however, should probably have been done on two patients with excessively large infants, one patient with an abnormal presentation, and one patient with uterine inertia.

Anesthesia and Analgesia.—It is difficult to assess the role of anesthesia and analgesia in perinatal mortality because of the multiplicity of factors that are so often present in an infant's death. However, each death was carefully reviewed as regards to the role played by anesthetic and analgesic agents. It was felt that there were no deaths in mature infants which were related to analgesic or anesthetic drugs. In 25 of the 45 premature infants who died in the neonatal period, however, mothers received at least one analgesic or anesthetic agent during labor. It is felt that this is not consistent with the best obstetric practice. In general, premature infants have the best chance of survival when no analgesia or anesthesia is used and delivery is conducted with the patient under a pudendal block and with administration of 100% oxygen.

Neonatal Deaths

The autopsy material and clinical records of the 63 neonatal deaths were reviewed in order to determine the causes of death of these infants. The major problems of the neonatal period were prematurity in 26 cases, birth injury in 13, and infection in 9. These and other factors in neonatal deaths are summarized in table 6.

Summary and Conclusions

A study of the perinatal mortality in 2,728 deliveries conducted in the North Carolina Memorial Hospital showed the principal causes of death to be hemorrhagic complications, toxemia of pregnancy, congenital malformations, and premature rupture of the membranes. It is felt that premature rupture of the membranes should receive increased attention as an important cause of perinatal mortality. There was a significant correlation between the socioeconomic status of the patients and perinatal mortality. The highest perinatal mortality occurred among the lower socioeconomic group of patients, whether the classification was based on the mother's education, on race, or on the father's occupation.

TABLE 6.—*Autopsy Findings or Clinical Diagnoses in Sixty-three Cases of Neonatal Deaths at North Carolina Memorial Hospital, 1952-1958*

	Total
Prematurity	26(41.1%)
Alone	9
With atelectasis	15
With ventricular hemorrhage	1
With adrenal hemorrhage	1
Postnatal asphyxia and atelectasis	3(4.8%)
Atelectasis alone	1
Hyaline membrane	2
Infection	9(14.3%)
Pneumonia with maternal sepsis	3
Pneumonia, cause unknown	2
Septicemia with maternal sepsis	1
Meningitis with traumatic delivery	1
Enterocolitis and pneumonia	1
Sudden death with tracheitis	1
Congenital malformations	8(12.7%)
Multiple, severe	2
Congenital diaphragmatic hernia	2
Polycystic liver and kidneys	1
Nephroblastoma and polydactyly	1
Esophageal atresia	1
Ileal atresia	1
Birth injury	13(20.7%)
Subarachnoid or subdural hemorrhage*	12
Traumatic delivery	1
Erythroblastosis	2(3.2%)
Fetal hydrops	1
Severe early jaundice and kernicterus	1
Sudden death with no significant findings	1(1.6%)
Unknown	1(1.6%)

* 11 in premature infants.

The principal errors in obstetric practice were related to the management of fetal distress, toxemia of pregnancy, and diabetes. A reduction in perinatal mortality can occur with improved obstetric care. This reduction will be most significant when it is associated with an improvement in the socioeconomic status of the obstetric patients and a reduction in the birth rate among indigent mothers.

North Carolina Memorial Hospital.

UROLOGIC PROBLEMS IN REHABILITATION OF HEMIPLEGIC PATIENTS

Edward J. Lorenze, M.D., Howard B. Simon, M.D.
and
Jack L. Linden, M.D., White Plains, N. Y.

The records of 254 patients with hemiplegia resulting from cerebral vascular accidents have been studied for evidence of an association between urinary incontinence and ability to regain ambulatory status. The patient who has had a stroke must be watched for evidence of urinary dysfunction, especially since incontinence may be evidence of retention. Its persistence is not always due to impairment of cortical control; it may be the result of coincident urologic disease. The data from this study showed that persistent urinary incontinence was associated with delay or failure of the recovery process with respect to ambulation, but the causal relation was complicated. The functions of ambulation and urination are both impaired by the loss of cortical control, but incontinence also causes difficulties in transportation and in rehabilitative procedures. The control of incontinence by the various measures suggested here is an important step in the rehabilitative process.

In a previous investigation[1] into the causes for failure to achieve independent ambulation in a group of hemiplegic patients, we noted that a high proportion of the patients with failures had associated urinary incontinence. Our purpose, therefore, has been to see if incontinence played a significant role as a cause for failure to achieve independent ambulation and to study the relationship of incontinence to other factors which are present, such as the mental status, emotional status, positive motivation for independence, severity of the muscular involvement, and aphasia. We were interested in the effects of the central nervous system lesions as well as in the possibility of local pathology within the genitourinary tract as further complicating problems. Some of these local pathological problems were preexistent to the hemiplegia, and others developed as complications of the stroke. In the past, it has been generally felt that persistence of incontinence is a poor prognostic sign for independence. We were interested in seeing if this were true on the basis of our own cases and in determining if there

Read before the Section on Physical Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

were other correlations which might be of value in prognosis as to recovery of bladder control and achievement of independent ambulation.

Method

We have reviewed the records of 254 consecutive inpatients admitted to the rehabilitation service of the Burke Foundation with the diagnosis of cerebral vascular accident resulting in hemiplegia. Patients were unselected and were not screened prior to admission. The cases were previously classified at time of discharge only in terms of ambulation as (1) success (completely independent with or without cane or brace), (2) premature discharge (insufficient time for recovery or therapy), (3) unfeasible for rehabilitation (general medical or mental condition unsatisfactory), (4) deteriorated (became acutely ill and therapy discontinued), or (5) failure. The failures, in terms of completely independent ambulation, were classified as "true failures" (TF) if ambulation was safely limited to parallel bars even with maximum support by a therapist, "assistance" (A) if patient required minimal assistance to give support or balance outside of parallel bars, or "observation" (OBS) if patient required observation outside the parallel bars to provide occasional assistance for balance and support. Patients in groups A and OBS generally could be expected to walk satisfactorily about the ward or home with an attendant or relative and thus are failures only in the sense of our definition of terms, the condition actually having improved significantly. Many in groups A and OBS also would be expected to continue to improve after discharge and ultimately arrive in our success group.

All patients who manifested urologic problems were analyzed as to success and failure in ambulation, diagnosis of urologic problems, age, sex, presence or absence of organic mental syndrome, emotional state, site of lesion, bilateral or multiple involvement, associated illness, recovery of urologic problems, and aphasia.

Physiology of Micturition

The bladder is controlled by two reflex mechanisms: 1. The spinal (cord) mechanism consists of an afferent and efferent limb synapsing in the sacral cord. Filling of the bladder is an adequate stimulus for this arc. When a sufficient threshold is reached the motor impulse is carried over the efferent limb resulting in contraction of the bladder detrusor urinae. 2. The suprasegmental (cortex, midbrain, and hindbrain) mechanism consists of afferent and efferent pathways between the brain and the cord. The afferent pathways carry the impulses of bladder sensation to consciousness, while the efferent pathways carry tonically active subconscious inhibitory impulses which prevent involuntary contraction of the bladder in adults and maintain sphincter tone.

Micturition results from a stretch reflex (spinal reflex) or the reaction by contraction of muscle fibers to the stimulus of stretching. The reflex center is in the sacral portion of the spinal cord. Impulses from the distending bladder wall constantly reach the reflex center, but stimulation of the efferent (motor) parasympathetic neurons to cause detrusor contraction is inhibited by impulses from centers in the brain or brain stem. This activity remains below the level of consciousness until vesical distention or intravesical pressure reaches a critical level, at which point the individual becomes aware of a desire to void. If the time and place are not propitious, inhibiting impulses may be sent voluntarily down to the sacral cord to postpone micturition. When desired, these impulses are suppressed and the detrusor muscle allowed to contract in response to the stretch reflex. Voiding is facilitated by contraction of the abdominal muscles and lowering of the diaphragm. The vesical neck gradually opens, the external sphincter opens abruptly, and voiding takes place. Contraction of the detrusor muscle is maintained until all of the urine is evacuated, and this is believed to be a manifestation of cerebral control.

TABLE 1.—*Types of Urologic Problems in Hemiplegic Patients During Rehabilitation*

Group	Patients, No.		Condition	Manifestation
	Men	Women		
Ambulatory	4	5	Loss of cortical inhibition	Incontinence of bowel and bladder
	3	1	Loss of cortical inhibition	Nocturnal incontinence
	1	...	Benign prostatic hypertrophy-prostatitis	Hematuria
	...	3	Cicatricial urethritis	Retention and incontinence
Nonambulatory	19	18	Loss of cortical inhibition	Incontinence of bowel and bladder
	1	...	Loss of cortical inhibition and postoperative carcinoma of prostate	Incontinence of bowel and bladder
	...	6	Loss of cortical inhibition and cicatricial urethritis	Incontinence of bowel and bladder and retention
	3	2	Loss of cortical inhibition	Nocturnal incontinence
	3	1	Loss of cortical inhibition	Urinary incontinence
	2	...	Benign prostatic hypertrophy	Frequency
	2	...	Vesical neck obstruction with benign prostatic hypertrophy	Slight retention and frequency
	1	...	Vesical neck obstruction with benign prostatic hypertrophy	Complete retention
	...	1	Postoperative retention	Frequency; dysuria
	...	7	Cicatricial urethritis	Retention and incontinence

Results

In our group of 254 hemiplegic patients, 138 achieved independent ambulation prior to discharge. This is the success group. One hundred sixteen patients did not achieve independent ambulation; 64 of these were in the failure group, due to the neuromuscular status, and 52 were considered to be in the unfeasible, deteriorated, or premature discharge groups. Of the total group of hemiplegic patients, 83 (32%) (table 1) were found to have had urologic problems during their period of rehabilitation. Of these, 17 were in the success group and 66 in the failure and unfeasible group.

The 17 patients in the success group who had urinary problems included 13 with lack of cortical inhibition, manifested in 9 by incontinence of bowel and bladder and in 4 by incontinence of bladder at night. This group consisted of 6 females and 7 males, and at the time of discharge 10 had become continent, 1 had improved, and only 2 remained incontinent of urine at night. The sex distribution of patients does not appear to be significant. There were 13 instances, however, of patients who manifested various degrees of organic mental syndrome and 8 instances of emotional disturbances which tended to clear up with improvement in control. Multiple strokes occurred in only one patient. Vesical neck obstruction occurred in three female patients in whom a diagnosis of cicatricial urethritis had been made. Manifestations included urinary retention, frequency, urgency, and incontinence, chiefly nocturnal. Two of these patients became continent and symptom free, and one improved after treatment. Benign prostatic hypertrophy occurred in one male patient and was manifested by gross hematuria which cleared spontaneously after a period of catheterization with an indwelling catheter. In neither the vesical neck obstruction cases or the benign prostatic hypertrophy case was an organic mental syndrome present.

TABLE 2.—*Characteristics of Continent and Incontinent Patients*

Group	Total	Hemiplegia		Organic Mental Syndrome	Emotional Disturbance	Bilateral Involvement	Multiple Involvement	Aphasia
		Right-Sided	Left-Sided					
Continent, successful rehabilitation								
Male	76	38	38	10	41	3	6	31
Female ..	45	17	28	3	22	2	6	14
Continent, unsuccessful rehabilitation								
Male	23	9	14	5	14	1	4	6
Female ..	27	12	15	5	16	2	3	9
Incontinent, successful rehabilitation								
Male	8	2	6	6	3	..	..	1
Female ..	9	5	4	7	5	..	1	2
Incontinent, unsuccessful rehabilitation								
Male	31	13	18	26	13	6	6	11
Female ..	35	18	17	27	15	5	5	17

The 66 patients in the failure group who had urinary problems included 52 with loss of cortical inhibition due to the cerebral vascular accident; this was manifested in 37 by incontinence of bowel and bladder, 4 by urinary incontinence—day and night, 5 by nocturnal urinary incontinence, and 6 by incontinence of bowel and bladder complicated by cicatricial urethritis.

Fourteen patients manifested primary urologic problems; seven females had frequency, urgency incontinence, and dysuria secondary to cicatricial urethritis, with retention of urine and cystitis. All of these patients became continent. Five males had retention with urgency incontinence and nocturnal incontinence with secondary retention and cystitis due to benign prostatic hypertrophy. One male initially showed bowel and bladder incontinence secondary to loss of cortical inhibition, but as this cleared he manifested a premorbid urinary incontinence which had been present after a prostatectomy for carcinoma with apparent sphincter injury. One female patient, who had undergone hamstring release, developed urinary retention postoperatively due to poor bladder emptying and developed a cystitis with urgency incontinence. After treatment she became continent.

There is no significant difference in the characteristics of incontinent males as compared to incontinent females in either the success or failure groups, with the exception that the males were slightly older. Males and females showed essentially the same incidence of right-sided and left-sided hemiplegia, aphasia, incidence of bilateral or multiple involvement, incidence of cardiovascular disease, emotional disturbances, and organic mental syndromes. There is no significant difference between the sexes in incidence of urologic problems in either the success or failure groups (table 2).

When we compare the success group with the failure group of incontinent persons, regardless of sex, there is no significant difference of incidence of right-sided and left-sided hemiplegia, organic mental deficits, or emotional disturbance, but there is an increased incidence of aphasia, second strokes, and bilateral involvement in the failure group as compared to the success group. It is felt the organic mental changes were more severe in the failures.

The outstanding fact noted is the much greater incidence of urologic problems in the failure group—66 cases out of 116, or 56%, as compared to 12% of the success group. This failure group is made up of those patients for whom rehabilitation is considered unfeasible and those patients who did not achieve independent ambulation by the time of discharge. Among the incontinent failures were 22 cases of multiple strokes or bilateral involvement. In the failure group of 31 patients with hemiplegia on the right, 28 had aphasia; in the successful group 3 cases of aphasia occurred in 7 patients. Thus, there was a higher incidence of aphasia in the failure group. Of the 67 incontinent failures, 53 showed organic mental changes, as did 13 of the 17 in the successful group. The primary cause was loss of cortical inhibition alone in 56 patients, with cicatricial urethritis in six and benign prostatic hypertrophy in one. Seven patients had cicatricial urethritis alone, and six had benign prostatic hypertrophy alone.

The continent patients, as compared to the incontinent, showed a majority of successes and a decreased incidence of organic mental changes, multiple strokes, and bilateral involvement. Aphasia in all groups occurred in a majority of patients with hemiplegia on the right; it did not appear to be significantly higher among the incontinent patients as such but was slightly higher in the failure group of both the continent and incontinent patients.

Observations After Cerebral Vascular Accident

During the initial phase of a stroke, with or without loss of consciousness, as a result of the neurological lesion, there is an interruption in the normal pathway of afferent impulses from the bladder wall to the cerebrum and the efferent pathways which permit cortical inhibition of the reflex of micturition. The loss of cerebral inhibition over reflex bladder contractions results in frequency, urgency, and urgency incontinence (precipitate micturition), not unlike that in a patient with uninhibited neurogenic bladder.

Bilateral lesions of the motor cortex usually give rise to such characteristic disturbances as (*a*) inability to initiate micturition voluntarily, (*b*) inability to stop the stream, and (*c*) urgency, frequency, and urgency incontinence due to lack of cerebral inhibition. The bladder is overactive and hyperirritable. The external sphincter may become hypertonic or even spastic with resultant retention.[2] The more extensive the lesion the more likely that bilateral dysfunction may occur, at least temporarily, and thus the greater likelihood of impaired cortical inhibition.

Thus, to a certain limited extent the situation is similar to that which occurs in a spinal cord transection with the development of an automatic bladder. In hemiplegia, of course, the situation is not as marked and generally there is recovery, since only the tracts of one side of the brain are affected and usually only temporarily. The loss of cortical inhibition of micturition permits the detrusor to contract frequently and with little force, thus giving rise to incontinence with urination occurring frequently in small amounts day and night. Normally, as the bladder fills and distends, cortical inhibition prevents urination through the action of the external sphincter and through inhibition of these mild detrusor contractions. Secondarily, in this phase, there is also a tendency for the bladder not to empty completely, so that there is usually some degree of residual urine. At times, urinary retention may be marked, particularly if some form of obstruction of the vesical neck is already present, and acute urinary retention may occur.

Prostatism in men is frequent in the stroke age group and contributes to retention, as does chronic cicatricial urethritis in the female. Retention may occur while the patient is unconscious, but with return of consciousness continued marked retention is uncommon, except in those with associated obstruction. After the acute phase of the cerebral vascular accident catheterization or an indwelling catheter may be necessary for prevention of the incontinence due to the loss of cortical inhibition, or it may be necessary also to prevent urinary retention due to this condition, plus a premorbid tendency to vesical neck obstruction which increases the amount of urinary retention.

Normally, as the patient regains consciousness and improves, cortical inhibition returns and the patient will regain normal bladder function. In a certain number of patients with hemiplegia, however, urinary incontinence continues as a problem. This is due to several factors, as follows:

1. The neurological impairment of the pathways may be such as to prevent normal function of cortical inhibition.
2. Organic mental changes with clouding of the sensorium or loss of motivation for control may cause the patient not to respond to the sensory stimuli of bladder distention and permit reflex emptying without cortical inhibition.
3. Preexisting vesical neck obstruction (such as prostatic hypertrophy in the male and cicatricial urethritis in the female) may have caused symptoms prior to the cerebral vascular accident. In these situations there has been urinary retention which leads to early attainment of the bladder threshold and hence frequent voiding. If the retention is marked, the patient may quickly reach a level of bladder distention which he is not able to control even if cortical inhibition is intact. Some of these patients, however, with only moderate retention, plus some loss of cortical inhibition, will develop frequency and urgency incontinence.
4. Local infection of the urethra, bladder neck, or prostate secondary to long-term or short-term retention or previous catheterizations adds to the symptomatology of frequency and urgency which may lead to incontinence at night when loss of cortical inhibition is most marked, whether due to psychological factors or to inherent neurological interference in the pathway.
5. Immobilization in bed, use of bedpan in supine position, weakness of abdominal and diaphragmatic contraction, lack of effort in attempting micturition through relaxation of sphincter and use of accessory muscles, and poor and ineffective detrusor contractions contribute to incomplete bladder emptying resulting in retention with tendency to cystitis, frequency, and urgency incontinence.

Management

If acute retention occurs, catheterization should be done every 8 hours, and if voiding is not spontaneous within 24 hours, an indwelling catheter may be used. After the patient has been fully conscious for 5 to 19 days, the catheter should be removed. Retention is uncommon, but if over 90 cc. of residual urine persists, the catheter should be replaced until the urologic problem is resolved. In such cases, the catheter must be irrigated daily with a bacteriostatic solution, such as benzalkonium

(Zephiran) chloride (1:20,000), and changed weekly. When the patient is able, habit training and supervised timed voidings will develop control.

If incontinence is a problem, check for retention, and if it is over 90 cc., replace the catheter temporarily. If the residual is small, incontinence is on the basis of poor cortical inhibition, and the catheter may be replaced temporarily to await further neurological recovery. The general condition should make it possible to decide on the necessity for an indwelling catheter. If possible, unless retention with infection is present, use of the indwelling catheter should be avoided.

Loss of cortical inhibition manifests itself in most severe form by bowel and bladder incontinence. Bowel incontinence can usually be brought under control first, both on an active and on a passive basis. This is done by achieving a bowel regimen with daily daytime evacuation, with use of bedpan or commode with suppository or enema as needed.

Bladder continence is achieved by stressing urination every two to three hours, synchronized to the patient's spontaneous detrusor contractions during waking hours, with late evening catheterization to remove residual and minimize nocturnal incontinence. When no residual occurs catheterization can be discontinued.

Trials without the catheter should be repeated periodically until the patient can do without or until neurological recovery has reached its zenith. If recovery has been poor and the patient still has urologic difficulty, prolonged catheter drainage (if there is a high residual of urine) or other device for incontinence, such as a rubber urinal, may be necessary. If recovery has been good but urologic difficulty persists, treatment for any underlying or preexisting uropathology should be instituted. In men, transurethral prostatic resection may be needed in those with benign prostatic hypertrophy. In women, urethral dilatation and local therapy to the bladder and urethra (nitrofurazone [Furacin] urethral suppository or dilute silver nitrate) may be helpful in cicatricial urethritis.

Parasympathicolytic drugs (such as methantheline [Banthine] bromide) are of little value usually when incontinence results from lack of cortical control rather than muscular hyperactivity, but they may be of symptomatic value in frequency secondary to low-grade infection. In this case, primary attention should be on culture of organisms and appropriate antimicrobial agents.

In all cases, after catheter removal, begin a supervised habit training schedule of voiding every two to three hours, gradually lengthening the intervals as recovery permits. Continual reorientation, encouragement, explanation, diminution of embarrassment, and use of sitting position, diaphragm, and abdominal muscles in voiding are essential in achieving urinary continence during recovery from loss of cortical inhibition.

With indwelling catheters, irrigate four times daily with sterile saline solution, boric acid, phosphoric acid, or half-strength G (Suby) solution. Also use ammonium chloride or methenamine mandelate (Mandelamine) to keep the urine acid. Change the catheter weekly, under sterile conditions. Intermittent prophylactic chemotherapy (full therapeutic dose for one week for each month) may be useful in lessening urinary tract infection.

Conclusions

The overwhelming cause of urinary incontinence was found to be loss of cortical inhibition, and urologic complications were usually secondary to this phenomenon. Frequency and dysuria frequently occurred as the result of preexisting vesical neck obstructive disease and/or infection. Recovery from loss of cortical inhibition usually followed in the following phases: bowel and bladder incontinence, bladder incontinence, nocturnal urinary incontinence, and normal bladder control.

The high incidence of incontinence among those hemiplegics who failed to achieve independent ambulation was noted in a prior study when the causes of failure to achieve independent ambulation were being evaluated. Despite the high incidence it is not felt to be a causative factor in itself.

Persistence of urinary incontinence is a poor prognostic sign, but it must be evaluated in terms of all other factors present. A few patients remained incontinent when they became ambulatory. In none of our patients was this considered the reason for failure to achieve independent ambulation by itself but it usually indicated organic mental changes, poor motivation, emotional problems, and/or severe neuromuscular involvement. In most situations where independent ambulation was not achieved, the patient had not only bladder incontinence but also bowel incontinence.

Incontinence has been found to retard and impede achievement of independent ambulation because it causes difficulties in transportation and management of the patient in various clinics and gymnasiums and diminishes the enthusiasm and positive motivation of both the patient and the therapeutic team. Most instances of incontinence can be improved to the point of no interference with the rehabilitation treatment program through a habit-forming bladder program, positioning, encouragement, assistive abdominal and diaphragmatic contractions to achieve full bladder emptying, continued efforts at progressive physical activity and ambulation, a bowel training program with achievement of fecal continence, and the correction of local pathological situations in the urinary tract.

D-PANTOTHENYL ALCOHOL IN MANAGEMENT OF PARALYTIC ILEUS

Joe W. Frazer, M.D., Benjamin H. Flowe, M.D.
and
William G. Anlyan, M.D., Durham, N. C.

The effectiveness of D-pantothenyl alcohol in the treatment of paralytic ileus was tested by comparing two groups of 50 patients after abdominal operations. Both groups received the customary postoperative care as seemed indicated by the attending surgeon, but in addition 50 patients received intramuscular injections of 250 mg. of D-pantothenyl alcohol every six hours until normal peristalsis was established, while the remaining 50 received a placebo in the same manner. In the group receiving the drug it was possible to discontinue the use of tubes and of venoclysis sooner than in the other group, but it was debatable whether the actual difference in the average case was of practical importance. The drug was used in 12 additional patients who had profound postoperative intestinal atony, and in each case it appeared to cause resumption of bowel sounds, passage of flatus, and relief from distention. No undesired side-effects were observed.

One of the distressing complications encountered after a surgical operation is adynamic ileus. Temporary paralysis of the intestine can result from direct injury to the intestine, chemical irritation, infection, reflex reaction to injury, and metabolic imbalances such as uremia and electrolyte deficiencies. Because of the serious consequences that may result from this complication, most surgeons today give considerable attention to its prevention. Modern practices of restoring good nutrition and blood volume before surgery, correction of electrolyte deficits, intestinal intubation, antibiotic preparation of the intestine, early ambulation, and other aids have helped in minimizing this syndrome.

Despite the infrequency of severe ileus, lesser degrees of intestinal paralysis are common. After any intra-abdominal procedure with its inherent trauma to the intestinal tract, a period of intestinal atony with mild distention may be expected. After this, many patients may have "gas pains" which usually herald the onset of intestinal peristalsis. The majority of patients then eliminate flatus and progress without incident to recovery of normal intestinal activity. For reasons that are not always clear, some patients have a delayed onset of peristalsis. They become distended and uncomfortable, necessitating the use of gastric suction, the rectal tube, enemas, and parasympathomimetic drugs. Most patients respond to these measures, but they are often physically exhausted by the regimen. Only the rare case is refractory and proceeds to true adynamic ileus. Any agent which would safely shorten the period of postoperative intestinal atony might decrease the discomfort due to the resumption of peristalsis and also be of value in the treatment of paralytic ileus. This study is an evaluation of an agent which may be useful in the prevention and treatment of paralytic ileus.

Review of Literature

D-Pantothenyl alcohol (Panthenol) is the alcohol of pantothenic acid, a vitamin of the B group. This vitamin, although included in most multi-vitamin preparations, has never been shown to be essential to human nutrition. It has been given to both animals and humans in very large doses with no toxic effects. Pantothenic acid is found in virtually every food eaten by man.

Early animal experiments demonstrated several interesting manifestations of pantothenic acid deficiency. McKibbin and co-workers[1] in 1940 described a deficiency syndrome in the dog which suggested to them a disorder of the parasympathetic nervous system. Bly and co-workers,[2] in 1943, using pantothenic acid-deficient dogs with jejunostomies, demonstrated a 50% decrease in intestinal motility and a 40% to 60% decrease in the absorption of carbohydrate and protein. Rats were fed a diet deficient in pantothenic acid by Jurgens and Pfaltz[3] in 1944 with the interesting finding of gas-filled atonic small intestines. This was alleviated rapidly by feeding pantothenic acid.

This latter study led Jacques[4] to use this vitamin in the treatment of adynamic ileus. He reported 16 severe cases with fecal vomiting that had not responded to all known therapeutic measures. Each patient was given 50 mg. of calcium pantothenate intramuscularly every three hours with uniformly good results. The passage of flatus, which Jacques considered the best sign of improvement, began 1½ to 13 hours after the initial injection. Banerji,[5] after reading Jacques' report, treated 19 patients with calcium pantothenate, with excellent results in 18. Favorable results in treating ileus with pantothenic acid were also reported by Zutelman,[6]

From the Department of Surgery, Duke University Medical Center.

Hofmann,[7] and Docherty.[8] The only report from the United States was by Bergman,[9] who treated 44 cases of ileus with favorable results. Felten [10] gave D-pantothenyl alcohol to 50 patients with severe gas pains, constipation, and distention after operation. He found that the majority expelled flatus in a few hours with marked subjective relief.

The uniformly good results reported seem to indicate that pantothenic acid is effective in restoring normal intestinal activity. The mechanism by which it exerts its effect remains unknown. Whereas pantothenic acid itself is not essential to nutrition, the discovery by Lipmann [11] of coenzyme A, which is a derivative of pantothenic acid, revealed the basic importance of the pantothenyl complex in cellular physiology. Coenzyme A is involved in the aerobic utilization of glucose, the synthesis of fatty acids, sterols, and steroids, and the acetylation of choline. It is this latter function which may be responsible for the action of D-pantothenyl alcohol in the intestinal tract.

Table 1.—*Type of Operations Performed on Fifty Patients Treated with D-Pantothenyl and Fifty with Placebo*

	Group 1, D-Pantothenyl		Group 2, Placebo	
Type of Surgery	No. of Cases	Av. Time to Pass Flatus, Hr.	No. of Cases	Av. Time to Pass Flatus, Hr.
Gastric	13	40	12	55

Peritonitis due to perforated viscus	3	36	4	91
Appendectomy	2	24	3	48
Total	50		50	

Materials and Methods

Group 1.—One hundred unselected patients undergoing various intra-abdominal surgical procedures were used as the primary group for this study. Each patient was prepared for surgery with the usual examinations and preliminary procedures. Identical multiple dose vials containing D-pantothenyl alcohol and a placebo were used. The identifying code was on a removable label. Material for treatment was supplied to the ward with only the patient's name, the code having been removed. A list of the patients and the agent used was recorded. The clinical observers were not aware of the nature of the drug being administered. Fifty patients received D-pantothenyl alcohol and 50 others the placebo. The initial dose was started in the recovery room immediately after each operation and was continued until normal peristalsis was restored. Dosage was standardized at 1 cc. or 250 mg. of the active D-pantothenyl alcohol every six hours intramuscularly; a similar volume of the placebo was administered.

Group 2.—A second group of 12 patients who developed varying degrees of postoperative intestinal atony were treated with 250 mg. of D-pantothenyl alcohol intramuscularly every six hours until normal peristalsis was established.

In a study of this type the most difficult aspect was the evaluation of subjective complaints in the face of the many variables inherent to the postoperative period. All patients were treated as seemed indicated by the attending surgeon. No measure was added or withheld from the patient because of this study. Intestinal tubes, enemas, and other aids were used as deemed necessary. As a measurable end-point indicating the desired effect of the drug, the time of onset of audible peristalsis and the time of passage of flatus were selected. These observations were usually made at 6-hour to 12-hour intervals.

Results

Group 1.—Of the 100 patients treated by the double blind control method, 50 patients received D-pantothenyl alcohol and 50 others the placebo. Comparison of these two groups reveals them to be similar in most significant clinical aspects, including age and sex. Since the factor most likely to affect intestinal motility in the postoperative period was the type and extent of the surgery performed, the similarity of both groups is compared in table 1. Such factors as the duration of the operative procedures, the type of anesthetic agent, and the general condition of the patient were recorded and found to be essentially similar in both groups.

The 50 patients receiving D-pantothenyl alcohol developed audible peristalsis in an average of 25 hours postoperatively as compared to 55 hours in the control group. The passage of flatus was noted at an average of 48 hours in contrast to 66 hours in the placebo group. Since the appearance of bowel sounds and the passage of flatus indicate a resumption of intestinal activity, the figures seem to reflect a shortening of the period of postoperative atony in the treated group. No patients in group 1 and six patients in the control group developed signs of early ileus in the late postoperative period.

Table 2 divides the patients in the treated and control groups into comparable age groups. The time required to pass flatus averaged at least 24 hours longer in the control group in each division. Age per se did not influence the period of postoperative atony in either group.

Since patients with intestinal surgery or peritonitis are most likely to develop intestinal atony, similar types of operative procedures are compared in table 1. Three patients with diffuse peritonitis due to perforated intestine were treated with D-pantothenyl alcohol with the passage of flatus in an average of 36 hours as compared to four patients in the control group with atony for an average of 91 hours. Resection of the intestine with anastomosis was accomplished in six patients treated with D-pantothenyl alcohol with the average time for passing flatus of 36 hours as compared with eight patients in the placebo group who required 75 hours to achieve the same result. In each group were four patients with mechanical intestinal obstruction relieved by operation. The four treated with D-pantothenyl alcohol were expelling flatus in an average of 24 hours, whereas the controls averaged 78 hours. The onset of peristalsis in the control group was similarly prolonged after gastric surgery, biliary surgery, appendectomy, and laparotomies for lesions not involving the intestinal tract.

Of the 50 patients treated with D-pantothenyl alcohol, only 1 developed nausea and vomiting. This case seemed to be a failure of treatment until obstruction of the gastroenterostomy stoma was demonstrated. After the obstruction cleared the patient proceeded to complete and rapid recovery. One patient undergoing a right colectomy had no peristalsis for four days but then progressed normally. In each of the 50 cases, after normal peristalsis returned, the patients continued to complete recovery with no later intestinal dysfunction.

Of the 50 patients treated with the placebo, 6 developed a recurrence of abdominal distention and absent bowel sounds after the usual period of postoperative atony had cleared. In three of these, gastric suction was reinstituted along with multiple enemas with clearing of the ileus within 48 hours. D-Pantothenyl alcohol, 250 mg. every six hours, was given to the other three after the drug code was broken. Two of these passed large amounts of flatus within 12 hours while the third was free of distention 36 hours after institution of therapy.

In evaluation of the more subjective data it was found difficult to grade symptoms. All patients complained of discomfort in the early postoperative period, but the majority in both the treated and control groups had minimal complaints after the first 24 hours. Complaints most often registered included abdominal soreness and discomfort from intestinal tubes and intravenous therapy. Nausea and vomiting were unusual after the immediate postanesthetic period. It was noticed that, once normal peristalsis returned, the patient usually felt better even when there were no specific complaints. In the treated group the earlier resumption of intestinal function allowed the earlier elimination of tubes and intravenous administration of fluids and thus in effect gave a measure of indirect subjective relief.

Group 2.—Of the 12 selected patients treated with D-pantothenyl alcohol because of profound postoperative intestinal atony, in each case abdominal distention, absent bowel sounds on auscultation, and marked subjective complaints such as abdominal discomfort, nausea, and fulness were present. These cases are presented briefly.

CASE 1.—A 12-year-old girl with a ruptured appendix had an appendectomy. Twenty-four hours after operation, marked distention with absent peristaltic sounds had developed despite intestinal suction. D-Pantothenyl alcohol was given, with resumption of bowel sounds after 3 hours and the passage of flatus after 12 hours. All distention had cleared and the patient felt greatly improved within 24 hours.

CASE 2.—A 22-year-old woman with acute pelvic cellulitis underwent exploratory laparotomy. Twenty-four hours after operation, marked distention was present and peristalsis was absent. Nausea and vomiting were severe. D-Pantothenyl alcohol was given, with the passage of flatus in 3 hours and clearing of all distention within 24 hours.

CASE 3.—A 30-year-old woman with carcinoma of the cervix had radical hysterectomy and lymphadenectomy. Twenty-four hours after operation, distention and a silent abdomen were noted despite intestinal suction. D-Pantothenyl alcohol was given with bowel sounds and passage of flatus within 12 hours. Normal peristalsis and a flat abdomen were noted within 24 hours.

CASE 4.—A 34-year-old man fractured his ribs on the left side. Three days after injury marked distention, a silent abdomen, and considerable discomfort had developed. Enemas, gastric suction, and rectal tubes had not helped. D-Pantothenyl alcohol was given, with the passage of flatus and subjective relief within 12 hours. All distention cleared within 24 hours.

TABLE 2.—*Age Distribution of Fifty Unselected Patients Treated with D-Pantothenyl and Fifty with Placebo*

	Group 1, D-Pantothenyl		Group 2, Placebo	
Age, Yr.	No. of Cases	Time for Passage of Flatus, Hr.	No. of Cases	Time for Passage of Flatus, Hr.
0-20	3	48	2	108
20-40	13	33	14	57
40-60	22	35	20	72
60-80	12	40	13	67
80 or over	0	...	1	60
Total	50		50	

CASE 5.—A 25-year-old man with intestinal obstruction secondary to adhesions after gastrectomy had lysis of adhesions. Three days after relief of the obstruction, the abdomen became markedly distended with hypoactive bowel sounds. A recurrent obstruction was suspected. D-Pantothenyl alcohol was given, with resumption of active bowel sounds and passage of flatus within 12 hours. All distention cleared within 36 hours with complete subjective relief.

CASE 6.—An 89-year-old woman with obstruction of the large intestine underwent loop colostomy followed by right colectomy. On the ninth day after the colectomy, bowel sounds disappeared and the abdomen became markedly distended and silent. It was feared that reintubation would be necessary. D-Pantothenyl alcohol was given, with the return of bowel sounds within a few hours, and flatus with a large bowel movement within 12 hours.

CASE 7.—A 31-year-old woman had tubo-ovarian abscess with peritonitis and underwent salpingectomy. Thirty-six hours after operation, marked distention, nausea, vomiting, and absent bowel sounds were noted. D-Pantothenyl alcohol was given followed within 6 hours by the explosive passage of flatus with clearing of distention within 24 hours.

CASE 8.—A 52-year-old woman with intestinal obstruction due to adhesions had lysis of adhesions. On the fourth day after surgery, distention was marked, with a silent abdomen. A single dose of D-pantothenyl alcohol was given with the passage of flatus in three hours followed by a bowel movement that evening.

CASE 9.—A 41-year-old woman with pelvic inflammatory disease had a hysterectomy. On the seventh postoperative day the patient developed fever, a silent abdomen, and distention. D-Pantothenyl alcohol was given with the passage of flatus within 3 hours and clearing of the ileus within 24 hours, even though her fever persisted until an abscess was drained four days later.

CASE 10.—A 40-year-old woman with carcinoma of the cervix had radical hysterectomy and lymphadenectomy. Thirty-six hours after operation she developed marked distention, with a silent abdomen. D-Pantothenyl alcohol was given with the passage of flatus within a few hours. The patient felt better within 24 hours, but 48 hours were required for the distention to clear completely.

CASE 11.—A 25-year-old woman with cholelithiasis had cholecystectomy. On the second day after operation she became distended, with no bowel sounds. D-Pantothenyl alcohol was given, with resumption of peristalsis within 12 hours and the passage of flatus within 24 hours.

CASE 12.—A 66-year-old woman with carcinoma of the ovary underwent total hysterectomy. Twenty-four hours after operation, marked distention and absence of bowel sounds developed. D-Pantothenyl alcohol was given, with resumption of good bowel sounds and the passage of flatus within 24 hours. All distention cleared within 48 hours.

In each case, D-pantothenyl alcohol appeared to produce a significant effect, although it was recognized that at least some of these patients might have improved spontaneously as rapidly without the drug. Further studies are needed, but the above cases are considered to be conclusive enough to treat subsequent cases of postoperative atony with this agent.

Side-effects.—Side-effects from the administration of D-pantothenyl alcohol could not be demonstrated. There was no complaint of excessive abdominal cramps, tachycardia, and flushing as is so often noted with parasympathomimetic drugs. At no time could symptoms be elicited due to an overdosage of the drug. No evidence of sensitivity, such as a rash, unexplained fever, or angioneurotic edema, was seen.

Comment

The inherent difficulty in evaluating any drug on the basis of clinical observation was apparent during this study. This difficulty was magnified during the postoperative period when so many variables were present, each affecting the well-being of the patient. It was felt, however, that this study represented an adequately controlled clinical evaluation.

D-Pantothenyl alcohol given in the immediate postoperative period appears to facilitate the resumption of normal peristalsis after operative procedures within the abdomen. It is debatable whether the actual difference in the average case is one of practical significance. The over-all difference demonstrated would not necessarily warrant the routine use of this drug in unselected cases. On the other hand, in the control group there were six patients who developed signs of early ileus in the late postoperative period who might not have had this difficulty if D-pantothenyl alcohol had been administered routinely. The prophylactic use of D-pantothenyl alcohol might be indicated in that group of patients in whom the type and magnitude of intestinal surgery is conducive to the development of paralytic ileus.

D-Pantothenyl alcohol gave excellent results in the 12 patients in group 2 treated for moderately severe intestinal atony as well as in 3 patients who developed distention after receiving the placebo. These findings are in agreement with the experience of other investigators. It would seem that D-pantothenyl alcohol is definitely indicated in those patients who appear to be developing postoperative distention. Certainly those patients with fully developed atony or classic adynamic ileus should be given the benefit of D-pantothenyl alcohol therapy.

The use of this drug is made more attractive by its apparent lack of toxicity as demonstrated both in this study and in the experience of others. The complete absence of abdominal cramps with tachycardia and flushing so often noted after the administration of a parasympathomimetic drug was striking. The most likely theory as to the reason for its effectiveness is that it stimulates the formation of acetylcholine through the coenzyme for acetylation (coenzyme A) of which pantothenic acid is a component. Thus the mode of action is through the "normal mechanism" controlling intestinal activity. The hesitation of many surgeons to use prostigmine-like drugs is often due to the fear that violent peristalsis might do damage to the operative site. D-Pantothenyl alcohol appears to be a safe yet effective agent capable of stimulating peristalsis and preventing paralytic ileus.

Summary and Conclusions

D-Pantothenyl alcohol and a placebo were administered alternately to 100 unselected patients undergoing intra-abdominal surgical procedures, utilizing the double blind control method. D-Pantothenyl alcohol appeared to shorten the duration of postoperative intestinal atony. Twelve other patients with moderately severe paralytic ileus were treated with D-pantothenyl alcohol. Within 24 hours, all 12 patients had resumption of peristalic activity as indicated by audible peristaltic sounds, the passage of flatus, and marked subjective relief. All distention had cleared within 48 hours. D-Pantothenyl alcohol appears to be a safe yet effective agent capable of stimulating peristalsis and preventing paralytic ileus.

Duke Hospital (Dr. Anlyan).

This study was supported by a grant-in-aid from Hoffmann-La Roche, Inc., who also supplied the D-pantothenyl alcohol used as Panthenol.

DISCOVERY OF TYPHOID CARRIER BY SEWAGE SAMPLING

Lois Ann Shearer, M.P.H., Alcor S. Browne, Ph.D., Robert B. Gordon, M.D.
and
Arthur C. Hollister Jr., M.D., Berkeley, Calif.

A method was applied for the bacteriological sampling of sewage through manholes at crucial points in an urban sewerage system in order to locate carriers of typhoid. The map shown here gives the arrangement of sewers in a city of 2,200 population where four cases had occurred in five years. The sampling method narrowed the field of inquiry to a small area, and bacteriophage typing of the Salmonella obtained yielded the final clue that led to identification of the carrier. The most significant advantage of this method is the ability to locate a carrier by use of a practical field study technique when the usual epidemiologic methods have failed.

In 1948, 1950, and 1952 Moore and his associates[1] reported the successful finding of typhoid and paratyphoid carriers by the continuous sampling of sewage for the presence of Salmonella. In their method, they suspended gauze strips (referred to as swabs) in the sewage flow and periodically removed and cultured them for Salmonella. Beginning at major sewage collection points, such as sewage treatment plants, they followed, as a consequence of positive findings, the source of organisms through lateral sewers to the homes of the carriers. Similar studies have been reported by a number of other investigators.[2] This sewage sampling procedure represents a new approach to the problem of locating carriers of enteric and other diseases in which the causative agent is present in the excreta. It also provides the epidemiologist with what appears to be an extremely valuable methodological tool.

Epidemiologic searches for carriers of enteric disease traditionally have followed a pattern of contact interviewing and analysis of the blood and excreta of suspected individuals. This method, although generally effective, has several drawbacks: 1. It may require a large number of trained field and laboratory workers. 2. Large numbers of specimens frequently must be obtained and processed before a positive finding is made. 3. People in the community are annoyed and sometimes alarmed by this type of investigation. Some individuals, especially those who have reason to believe that they themselves may be carriers, often refuse to cooperate. 4. A not unusual situation is the inability to locate the carrier by traditional epidemiologic methods in spite of repeated outbreaks of typhoid.

For some time the California State Department of Public Health has been interested in the swab technique. An opportunity to study and utilize the

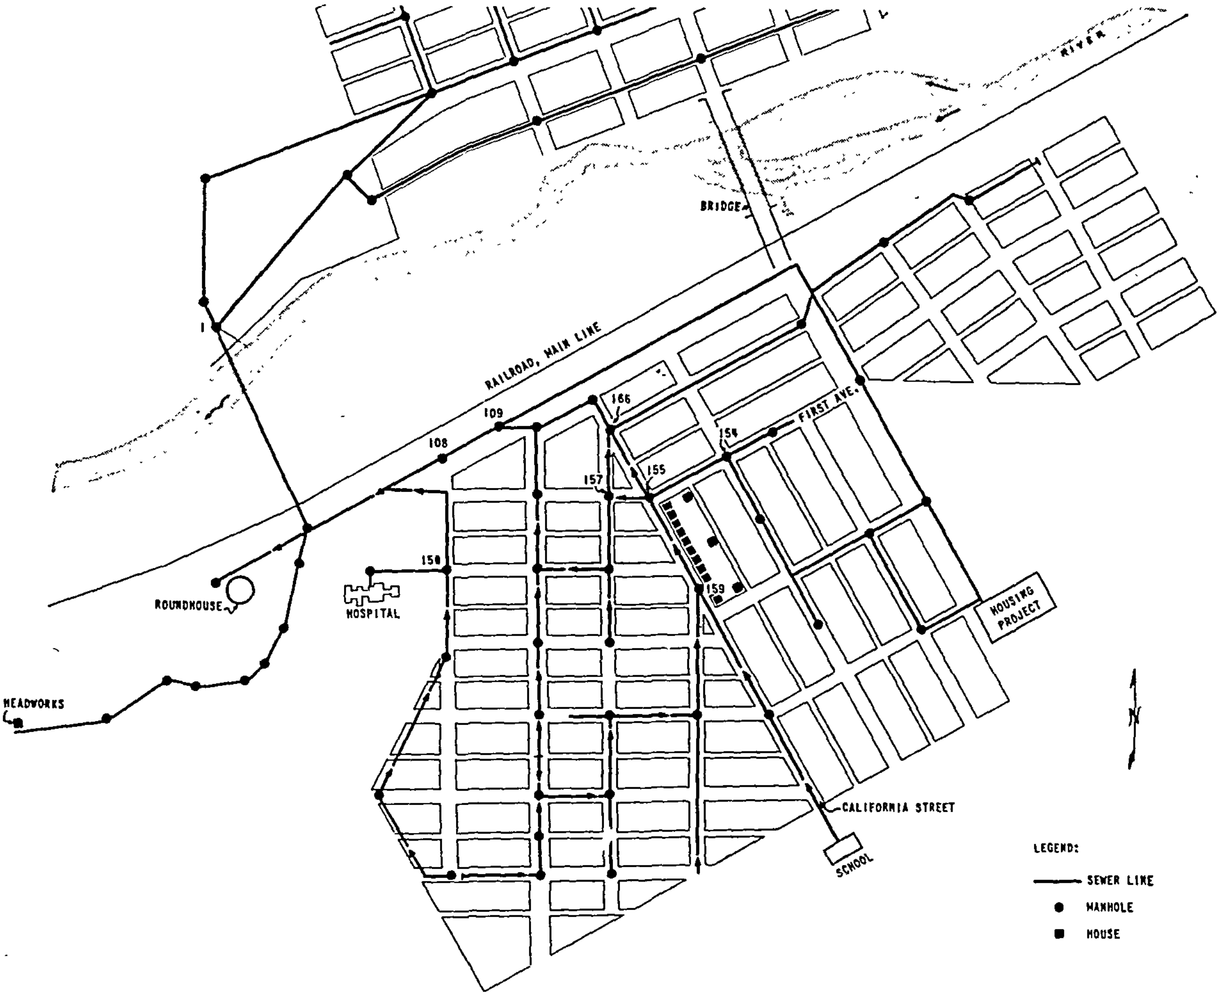
sewage sampling method was presented to the department in the summer of 1956. In and near a city of 2,200 population in the High Sierra country of California, a small but intermittent number of cases (four in five years) of typhoid had been reported over the preceding several years without discovery of the source of the infection. Because of the cooperation offered by the local governing and health officials and an engineering knowledge of the sewer system, it was felt that this community represented an excellent site for such a study. The major industries were railroading and lumbering. In addition, because of the plans to develop this community into a resort center, it was felt advisable to locate the possible carriers with as little contact as possible with the general public. A team consisting of physicians, nurses, microbiologists, and sanitary engineers was formed to make this study. The epidemiologic story is recounted here. Details of specific laboratory techniques will be reported elsewhere.[3] The sanitary engineering aspects have been reported by Greenberg, Wickenden, and Lee.[4]



Map of principal sewer lines and manholes in city where sewage sampling was done and discovery made of typhoid carrier.

Method of Study

Since there was no information available which would suggest the area in which the carrier (or carriers) resided, it was necessary to hold the entire town suspect. Even this assumption was somewhat dubious since the possibility could not be ruled out that the source of the cases was an itinerant, possibly a railroad worker. Preliminary work consisted of studying maps of the sewage system of the city and locating and opening certain manholes which appeared to be in key locations. Difficulties were encountered in finding some of the manholes which were covered with earth or asphalt. In these cases, a mine detector was used to locate the manhole. Other manholes were "dry," a result of obstructions in the lines, while others which were on the maps apparently did not exist at all.

When the preliminary work was completed, a mobile bacteriological laboratory was brought to the site of the investigation. Swabs consisting of pieces of fine mesh surgical gauze folded into eight thicknesses, 6 in. long by 4 in. wide, were prepared. These were attached to strings and placed in the sewage stream at manholes which were selected to provide a survey of the Salmonella content of the entire sewage system. The figure shows the principal sewer lines and location of manhole 108. The swabs were removed after 48 hours and taken to the mobile laboratory where they were examined by the method of Moore and co-workers,[1c] as modified by the Division of Laboratories of the California Department of Public Health.

On July 9, only three days after the sampling began, a culture positive for Salmonella typhi was obtained from the head works (see figure) of the sewage system. While it had no value for localization, it was encouraging to know that there was probably a typhoid carrier in the community and that the method was capable of detecting his presence. There were no further findings of S. typhi until July 14, on which day the swab in manhole 157 yielded a positive culture. A day later, July 15, the swab in manhole 108 was found to be positive, and on July 16 positive cultures were obtained from manholes 109 and 166. During this period daily swab samples were collected from selected manholes in the northern portion of the city and from manhole 1, through which the entire sewage flow from that part of the city passed. These swabs were consistently negative and as a result further work was limited to the southern portion of the city, although surveillance was maintained at manhole 1.

When the presence of a typhoid carrier had been indicated, the field investigation was suspended temporarily, so that further plans could be developed for research purposes and additional characterization of the organism which had been found could be obtained.

Phage typing, which was considered essential, was attempted in our laboratory by multiple pickings from each culture, but the organisms were found to be "untypable" by phages at our disposal, although they all appeared to be identical and to belong to group D. Cultures were then submitted to Dr. Philip R. Edwards of the Communicable Disease Center of the United States Public Health Service in Atlanta, Ga., who reported all organisms to be members of phage group D. However, in addition to the lysis of phages which placed the cultures in group D, the cultures were lysed by a phage identified as Utrecht 9 described by Scholtens.[5] This phage type had been found by Scholtens in two epidemics and a few isolated cases in Holland and is not known to have been reported from any area in the United States. In view of this successful typing, a culture isolated from an acute case of typhoid in the area during the previous year and reported then as "untypable," was resubmitted to the Communicable Disease Center. Interestingly enough, it was also typed by Utrecht 9. After the clinical illness this patient had been released from surveillance with a negative stool culture. At the time of the study, control swabs were placed in the manhole outlet through which sewage flowed from the household of this known ex-case. All of these swabs were negative.

In August the field crew and mobile laboratory returned and active sampling was resumed. On the 5th, 6th, 16th, 17th, and 18th of August, the swab from 156 was positive for S. typhi. On the 16th, swabs from manholes 157 and 155 were also positive. As seen from the figure, the sewage from the hospital and part of the southwest section of the city passed through manhole 156. The flow from this manhole, as demonstrated by placing dye in the hospital sanitary system, is direct to the main line of the sewer system.

Swabs from manholes 159 and 154, both of which drained into 155, remained negative while under constant surveillance. This tended to place the carrier somewhere in the immediate drainage area of manhole 155, which is the most distant point in the system from which positive findings were obtained. Swabs were then placed in manhole 155 in such a manner as to get separate samples of the flow from the two feeding sewers. The swab from the California Street sewer was positive while the swab on First Avenue remained negative. This further located the carrier on California Street between manholes 155 and 159, which area involved only the small group of homes shown on the map.

Since the phage type identified had previously been reported only from Holland, we attempted to determine if anyone from this block had resided in Holland and/or had symptoms of typhoid. A roster was prepared of patients and staff present in the hospital during the period that positive findings were obtained in manhole 156. This was compared with the list of people living in the suspect block. One individual was found to have a common link and to fit this pattern. Inquiry then revealed a 77-year-old retired railroad worker who had been in the hospital for the treatment of hypertension and congestive heart failure during the period that typhoid had been isolated from the hospital manhole and who also lived in the suspected residential area. During his hospitalization he was treated for cardiac disease, but his role as a typhoid carrier was not suspected. He came to this country from Germany 50 years ago and both before and after had traveled extensively as a sailor. While in Germany he had lived in the same house with a person from Holland who was known to have typhoid. The patient stated, however, that he had never had any symptoms of the disease himself. Stool specimens were obtained from him and readily yielded S. typhi, of the same phage pattern as the cultures isolated from the sewers, thus confirming him as the carrier being sought. The carrier was hospitalized Aug. 3 to 18. In view of the evidence presented by Harvey and Phillips [2a] that S. paratyphi B may survive for periods of 10 weeks in sewers in the absence of contamination, a positive sample from 155 on the 16th was considered possible.

Comment

One of the principal advantages of the method presented herein is the localization of carriers of enteric disease without invasion of the household or of the privacy of individuals and without undue public alarm. Just how far it is possible to proceed in localizing individual carriers depends on such variables as the construction of sewer systems and access to manholes. In Sidmouth, England, where Moore [1a] made his studies, it was possible to place swabs in access holes of individual house drains, thereby localizing the source to individual houses. On the other hand, presence of houses with individual privies or cesspools would preclude such a method of mass surveying, unless, of course, there was seepage into a stream or other body of water which in turn could be tested by the swab technique.

In this study it was felt that the practical limit of usefulness of the sewer system survey had been reached when the carrier was localized to one block. However, at this point, several methods for the further pinpointing of the source without any intrusion upon the population were apparent. The first and most attractive of these alternatives was previously described; the utilization of the limited geographical distribution of the phage type of the isolated organism. Although phage typing is an essential part of an epidemiologic study of a typhoid outbreak, this to our knowledge is the first time that the phage type presented the clue that led to the presumptive description of the carrier.

Another procedure was considered but not found necessary to use in this particular situation. This would have been to pass a line to which was attached a number of swabs through the sewer in the direction of sewage flow so that one swab rested in front of each house. By withdrawing the line at the insertion point it should have been possible to detect the house which presumably was the source of the Salmonella, since it should be at the point of the first positive swab on the line. Should all indirect methods have failed it would, of course, have been possible to interview and collect stool specimens from the individuals in the limited number of suspected houses. Similarly, swabs could have been placed in individual toilets, then collected and cultured, as was done by Kwantes and Speedy.[6] This was actually performed in the town after the conclusion of the major portion of the project, and positive findings showed that this too would have been epidemiologically feasible.

Since this project was initiated as a study in methodology, other problems were investigated. One was to determine if grease which commonly accumulates on the insides of the sewers could act as a trap for the typhoid organisms, as has been suggested by Harvey and Phillips [2a] and by Browne and Greenberg.[7] The latter found that an appreciable number of sewer grease samples which had been washed up on beaches near sewer outfalls were contaminated with Salmonella. Accordingly, samples of floating grease, as well as "wipes" of the walls of accessible pipes, were obtained. A significant number of positive findings were made by this method, especially by the wipes. Further studies are under way on the value of direct grease sampling. If this proves successful it would eliminate the time and labor necessary for placing and removing swabs. It would also serve as an index of the Salmonella present in the sewer prior to the start of the studies.

Another question which was studied was the possibility of sending the samples directly to the State Central Health Department Laboratory, in this case 200 miles from the site. Duplicate swab samples were taken and one was analyzed in the mobile laboratory while the second was shipped by express to Berkeley in a portable icebox. On only one of the 275 duplicate samples submitted did the two laboratories differ in their findings.

Summary

A study was made of the feasibility of searching for typhoid carriers by culturing samples of sewage taken at different points within a city. In this instance, it was possible to localize the residence of a carrier to a single block. Further localization was rendered unnecessary when positive specimens were found in the sewage outflow from the community hospital and the name of a resident of the suspected block was found in the hospital roster. Direct stool cultures from this man showed him to be a typhoid carrier, and phage typing of the organisms indicated that he probably had acquired his infection many years previously in Europe. Localization was also accomplished by household toilet swabs. The method has proved feasible as a practical field study technique.

FAILURE OF PENICILLIN IN TREATMENT OF ACUTE GONORRHEA IN AMERICAN TROOPS IN KOREA

Capt. Ernst Epstein (MC), U. S. Army (Res.)

The results of treating patients with acute gonorrhea by five daily intramuscular injections of 600,000 units of procaine penicillin G were followed up in 148 men. The treatment failed in 30. In 13 of these a second course was given. It was successful in nine, and in the four cases of failure cure was obtained with oxytetracycline. In 17 men the initial course of penicillin which failed was followed by treatment with oxytetracycline; this was successful in 15 cases, and in the 2 men who were not cured by it treatment with chloramphenicol was successful. Two cases of failure of penicillin are cited to illustrate the course of the infection. The present high rate of failure with repeated doses is in marked contrast to the much lower rate of failure with single smaller doses reported elsewhere two years ago. This evidence that a penicillin-resistant strain of Neisseria gonorrhoeae has emerged is of grave significance.

The remarkable response of gonorrhea to penicillin has long been emphasized, and it is usually held that penicillin-resistant Neisseria gonorrhoeae do not appear. However, in Korea failure of gonorrhea to respond to an adequate course of penicillin treatment is not uncommon. Not infrequently, military physicians in Korea encounter in soldiers cases of acute gonorrhea which persist in spite of 5 or even 10 daily injections of 600,000 units of an aqueous solution of procaine penicillin G.

Materials and Methods

This paper is a report of failures of penicillin therapy in cases of acute gonorrhea among United States troops in Inchon, Korea. Inchon is a major Korean port with about 2,000 military personnel, nearly all Army, receiving medical care from the Army dispensary. The study covers a three-month period, from Jan. 1 to April 1, 1958, during which 165 cases of acute gonorrhea in these troops were treated. An adequate follow-up study was possible in 154 cases, and this is the number of cases analyzed. Since the only reason for inadequate follow-up study was the movement of patients to another area, discounting these cases should not bias the results.

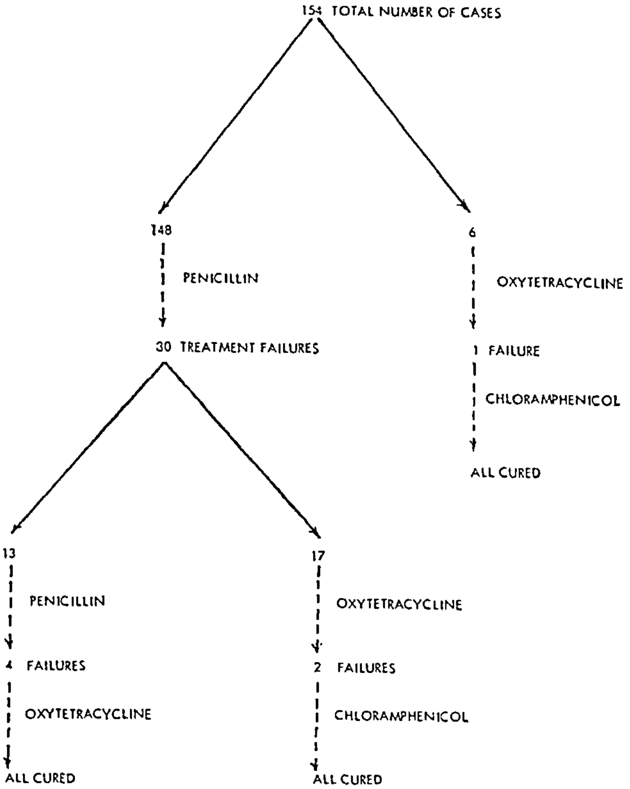
All cases represented acute gonorrhea with sudden onset of a purulent urethral discharge. In every case a history of recent sexual intercourse was obtained. Eight patients in this series had two cases of gonorrhea during the three-month period; therefore, a total of 146 persons were involved. These eight cases were felt to be reinfections and not treatment failures, since all of the patients had been asymptomatic for a period of at least two weeks after completing treatment and in seven of the eight a history of sexual intercourse after treatment was elicited.

Diagnosis.—The diagnosis of gonorrhea was made by the demonstration of characteristic biscuit-shaped, gram-negative, intracellular diplococci in Gram-stained urethral smears. All smears were examined by the same experienced technician. Smear findings in all cases of failure of treatment were confirmed by myself.

Treatment.—All patients with gonorrhea were given a printed sheet of directions and also instructed verbally to (1) be sure to take all five injections of penicillin, (2) return for reexamination three days after the last injection, and (3) abstain from alcohol and intercourse for two weeks. They were also given two weeks of medical restriction to their compound. No restrictions of other physical activities or exercise were imposed.

Except for those with a history of penicillin allergy, all patients received five daily intramuscular injections of 600,000 units of an aqueous suspension of crystalline procaine penicillin G. Only penicillin well within the expiration date was used.

Patients allergic to penicillin received a course of oxytetracycline therapy, 500 mg. four times a day for four days and then 250 mg. four times a day for three days. Patients treated with chloramphenicol were given 500 mg. four times a day for four days.



Type of treatment and results in 154 acute cases of gonorrhea.

Follow-up Study.—In order for the results of therapy to be evaluated, patients were entered on an injection record and this was checked daily for missed injections. Patients who failed to take the injections were called in and scheduled for additional injections to give a total of five treatments.

Any patient who was asymptomatic and free of discharge on examination three or more days after his last injection was considered cured. If a slight discharge persisted, at least two and usually three smears on different days had to give negative findings for N. gonorrhoeae before the patient was considered cured.

Results

The type of treatment and the clinical results are illustrated in the figure. In one of the six patients receiving oxytetracycline a relapse occurred and a course of chloramphenicol therapy was required for cure. Of 148 persons who received penicillin, 30 were not cured.

These 30 patients in whom penicillin treatment failed were divided into two groups, with 17 receiving oxytetracycline and 13 given a second course of penicillin therapy. Of these 13, 4 were not cured by this second course. They subsequently responded to a course of oxytetracycline therapy. In the group of 17 treated with oxytetracycline, 2 were not cured. Both were successfully treated with chloramphenicol.

In none of the 30 patients in whom penicillin treatment failed could a history of further sexual contact be obtained, even with careful inquiry. In two cases some doubt remained as to whether reinfections rather than treatment failures had occurred, since the interval between the last injection and the finding of a smear positive for N. gonorrhoeae was 11 and 13 days, respectively—considerably longer than in the other instances.

In the other 28 patients the time between the last injection and demonstration of positive smear results varied from zero to eight days, with an average of four days. In 14, N. gonorrhoeae was demonstrated in the smear zero to three days after the last penicillin injection. This interval could probably have been reduced somewhat with closer follow-up examinations of patients, since not infrequently a discharge had been present for a few days before the patient reported it.

Failure to receive all penicillin injections cannot account for the 30 instances of relapse, since only two patients missed one injection while two others missed two injections. These injections were made up, but a lapse of one or two days in the course of treatment in these four patients did result.

One interesting observation in the patients in whom penicillin treatment failed was that the character of the discharge often changed from thick and purulent to relatively thin and mucoid. The clinical picture changed from that of acute gonorrhea to one resembling nongonorrheal urethritis or chronic gonorrhea. Also, not infrequently a smear done early in the stage of treatment failure would be negative, while on repeat smear a day or two later myriads of typical intracellular diplococci would be apparent.

In 140 of the cases it was possible to examine the charts one month later for complications. There were eight penicillin reactions, an approximate incidence of 5%. All of them were mild, the chief manifestation being urticaria. Nongonorrheal urethritis occurred in 16 or about 10% of the cases. Additionally, there were two cases of epididymitis, one of prostatitis, and one of sterile injection site abscess.

Report of Cases

In most of the patients with treatment failure the discharge disappeared after one or two injections, only to return after treatment had been completed. The following case is typical.

CASE 1.—An 18-year-old boy was seen on Jan. 29, 1958, with a purulent urethral discharge which had begun the day before. He had had frequent sexual contacts, the most recent being four days previously. A smear proved positive for N. gonorrhoeae, and he was given a course of penicillin therapy. Three days after his last injection he reported with a small amount of moderately thick discharge. He denied further intercourse. Check of injection records revealed he had received all five injections. He stated that the discharge stopped on the second or third day of treatment but returned two days after his last injection. The smear was positive for N. gonorrhoeae. He was given a second course of penicillin treatment, and a final examination two weeks later revealed him to be asymptomatic and free of discharge.

In some of the failures the discharge diminished but did not disappear under treatment. In a few of these cases it was possible to demonstrate N. gonorrhoeae in the discharge while the patient was undergoing treatment. Details in one of these cases are given below.

CASE 2.—A 23-year-old man reported with a purulent urethral discharge on Feb. 10, 1958. He had been stationed in Korea since May, 1957, but had had no previous venereal disease. The discharge began the evening before, sexual intercourse having occurred six days previously. A smear was positive for N. gonorrhoeae. A course of penicillin therapy was prescribed. He returned on the fifth day of treatment with a persisting discharge which was positive for N. gonorrhoeae. He had received all five injections. He was given an additional five days of penicillin therapy. On the 10th day of penicillin treatment (Feb. 19), he reported that his urethral discharge had not disappeared. Smear revealed numerous pus cells and extracellular gram-negative diplococci but no intracellular forms. A repeat smear the next day was positive for N. gonorrhoeae. A course of oxytetracycline therapy promptly cleared his discharge. A final examination 18 days later (March 10) revealed him to be asymptomatic and free of discharge.

Comment

A 20% treatment failure rate is both unusual and unsatisfactory. Gjessing[1] reported a relapse rate of only 2.9% in 1,115 male patients with acute gonorrhea treated by the venereal department of the Bureau of Public Health, Oslo, Norway. A single injection of 300,000 units of procaine penicillin G was employed. In a series of 424 men treated similarly by the venereologic outpatient department of Marselisborg Hospital, Aarhus, Denmark, Nørgaard[2] reported 5% as having recurrences. Lodin[3] noted one recurrence among 78 Swedish male military recruits treated in the same way.

In the studies cited above the treatment failure rate varied from 1 to 5%; yet, although we used 10 times as much penicillin, 20% of our patients were not cured. That individual variation in penicillin metabolism, exercise, and alcohol consumption cannot account for this discrepancy is clear, since all these series involve mainly young males treated as outpatients.

The question that arises is whether these cases represent gonorrhea or some other disease. That is, how accurate is our diagnosis? The fact that bacterial culture studies were not done will no doubt be held, by some, as contributing to failure to establish the diagnosis. In males the finding of typical gram-negative intracellular diplococci is a practically absolute diagnostic criterion.[4] As Pelouze[4] and others have pointed out, all these criteria must be rigidly adhered to, since urethral exudates are frequently filled with extracellular, and even occasionally intracellular, cocci other than N. gonorrhoeae. To insure a correct diagnosis, I insisted that only a smear showing intracellular, gram-negative diplococci, of typical morphology, could be labeled as positive for N. gonorrhoeae.

Without a doubt, cultures would have been helpful. But the value of cultures for N. gonorrhoeae in a male is not to confirm a positive smear but to detect those cases of gonorrhea which yield a negative smear. Therefore, any error introduced by relying only on smears would give a falsely low value for the number of treatment failures. In an attempt to overcome this handicap, repeated smears were done on post-treatment discharges which were negative for N. gonorrhoeae at the first follow-up smear. However, no doubt an occasional case of post-treatment discharge labeled as nongonorrheal urethritis may have been an undetected treatment failure.

If, indeed, the treatment failures represent persistent gonorrhea, what evidence is there that these are not reinfections? It is, of course, impossible to prove that reinfection could not have occurred in each and every treatment failure. In order to rule out reinfection as far as possible, all patients were restricted to army compounds for two weeks and carefully questioned regarding further sexual contacts. Patients with gonorrhea are quite anxious while undergoing treatment, and, for a short while at least, follow instructions. These considerations do not rule out the possibility that an occasional treatment failure was the result of reinfection. However, they do eliminate reinfection as an explanation for the 20% failure rate.

It should be pointed out that reinfection cannot possibly explain treatment failures in patients in whom N. gonorrhoeae was demonstrated in the discharge while the patient was on penicillin treatment. The daily dose of penicillin used is several times as great as the amount needed for effective prophylaxis of gonorrhea.

Failure of penicillin in the treatment of gonorrhea is a common experience in the Far East. The chief of the urology service at the U. S. Army's

121 Evacuation Hospital in Korea has frequently encountered penicillin treatment failures.[5] Kern[6] reported nine failures in 59 consecutive cases of gonorrhea treated in the port city of Pusan, Korea. Treatment was identical with that used in this study. Sabath[7] had a failure rate of over 30% among troops in the First Cavalry Division area in Korea treated with three daily injections of 600,000 units of procaine penicillin G in oil with 2% aluminum monostearate.

It seems to me that these cases of penicillin treatment failures can only be explained on the basis of penicillin-resistant strains of N. gonorrhoeae. When referring to penicillin resistance, increased relative resistance is meant. That is, a significantly higher concentration of penicillin is required for an antibacterial effect than is the case with usual strains of N. gonorrhoeae. Surprisingly, until recently there were practically no reports on penicillin-resistant N. gonorrhoeae in the literature.

From Great Britain, King[8] reported in March, 1958, "There is evidence that penicillin-resistant strains of gonococci are now emerging. Some cases of acute gonorrhœa fail to make any response to doses of penicillin which in the past were nearly always highly efficacious. Repeated doses of penicillin and doubling the doses may have no effect. In other cases, response seems satisfactory but relapse follows within a day or two. Quantitative in-vitro tests for sensitivity to penicillin suggest that in these cases organisms from the secretions are considerably less sensitive to penicillin than the Oxford staphylococcus or other strains of gonococci."

Cradock-Watson and co-workers[9] noted an apparent increase in penicillin treatment failures in England in a recent report of 200 cases. In vitro sensitivity studies, when compared to the clinical results, showed most of the failures to be in the relatively small group of patients who were infected with the more penicillin-resistant strains.

Bernstein[10] recently completed a thorough study of the bacteriology of penicillin treatment failures among United States military personnel in Japan. He demonstrated in vitro resistance of certain strains of N. gonorrhoeae to penicillin. Furthermore, the results of these in vitro sensitivity studies, when combined with blood penicillin level determinations, correlate well with the clinical course of the patients with penicillin treatment failures. He has shown that those in whom penicillin treatment has failed can be cured with penicillin providing it is administered in doses which raise the blood penicillin level sufficiently to overcome the penicillin resistance of N. gonorrhoeae. Bernstein also considers the repository form of penicillin to be of little value, since it does not raise the blood penicillin level sufficiently.

Although many authorities recommend treatment of acute gonorrhea in the male with a single injection of 600,000 units of repository penicillin, this has been abandoned by most military physicians in Korea. I have found procaine penicillin G in oil with 2% aluminum monostearate disappointing. Not only are treatment failures more common, but the clinical picture is obscured by the more prolonged suppressing action of the repository form of penicillin.

In this study, oxytetracycline was used a total of 23 times, with three failures. I believe that these failures are due to resistance of N. gonorrhoeae rather than to the patient's failure to take the medicament. When used in amounts of 2 Gm. daily, in divided doses, broad-spectrum antibiotics not infrequently fail to cure when penicillin treatment has failed. Others have had the same experience, even though this treatment was continued for seven days.[11] Although, in my experience, chloramphenicol had cured about 10 times when penicillin had failed, Romsey,[5] as well as Bernstein,[10] have reported occasional failures with chloramphenicol.

From the clinical standpoint, the emergence of penicillin-resistant strains of N. gonorrhoeae has grave significance. No longer can acute gonorrhea be considered lightheartedly as a disease with a certain cure and less disability than a common cold. The twin problems of chronic gonorrhea in the male and the asymptomatic male carrier, which had been largely banished by penicillin, have returned. It is probably only a matter of time until penicillin resistance will be met on an increasing scale all over the world. Furthermore, careful and prolonged follow-up studies will be necessary. In all likelihood various types of "provocative" tests will again have to be performed to ascertain a cure.

Summary

Among a series of 146 male military personnel treated for acute gonorrhea in Inchon, Korea, 30 (20%) failed to be cured by a course of five daily injections of 600,000 units of crystalline, aqueous, procaine penicillin G. It is felt that increased penicillin resistance on the part of Neisseria gonorrhoeae is the probable cause of these failures. Since penicillin may produce a suppressing, but not curative, action on gonorrhea, careful follow-up studies are important.

CLINICAL NOTES

SCREENING FOR DIABETES BY THE GLUCOSE OXIDASE METHOD

Melvin M. Chertack, M.D.
and
Joseph C. Sherrick, M.D., Chicago

Recently there has been increasing interest in screening programs for diabetes, and several different screening methods have been advocated.[1] The results of screening programs differ considerably, depending on the age, weight, and family history of the group screened; on the type, technique, and standards of screening; on the extent of diagnostic evaluation; and on the diagnostic criteria for diabetes mellitus used in the program.[1a]

Although there is disagreement as to the choice of a screening procedure, certain general principles are acceptable to most authorities.[1c] It is generally recognized that, while the glucose tolerance test would be the ideal procedure, it is too expensive and too complicated for most large-scale programs. The combination of a urine sugar test and a postprandial blood sugar test is considered to be one of the most effective methods, but this has a limited application because of the necessity of obtaining a blood specimen. It is obvious that the urine sugar test is simpler and less expensive than the above procedures. However, heretofore only the copper reduction method has been available. This test is not specific for glucose, giving positive results with fructose, lactose, and other reducing substances.[1c] In addition, this technique tends to detect frank diabetes but to overlook mild or latent cases in which early treatment may be indicated.

Recently, specific enzymatic tests for glucose have become available.[2] These enzymes are flavoproteins which catalyze the aerobic oxidation of glucose to gluconic acid with the production of hydrogen peroxide. The presence of glucose in urine is detected by color changes of reagent-treated paper. The enzyme tests are specific for glucose in amounts as small as from 0.01 to 0.1%. Negative results have been obtained in the presence of lactose, fructose, xylose, mannitol, acetylsalicylic acid, amphetamine, barbiturates, sulfonamides, quaternary ammonium compounds, and hexylresorcinol. In view of the specificity of these tests for glucose, it was considered worthwhile to conduct a detection survey utilizing them in comparison with a copper reduction method.

Materials and Methods

The survey was held during Diabetes Detection Week. A booth was set up in the lobby of the University of Illinois Research and Educational Hospitals, and personnel associated with the professional schools were urged to bring a urine specimen to the booth one hour after a full meal. The specimens were tested for reducing substances by a commercial copper sulfate tablet test (Clinitest) and for glucose by two glucose oxidase tests (Clinistix and Tes-Tape). If the result of any one of the three tests was positive, a glucose tolerance test was done. The "true glucose" method of Somogyi-Nelson[3] was used for determination of the blood glucose level, and the glucose tolerance test was done as follows: a fasting venous blood specimen was obtained, a calculated dose (1 Gm. per kilogram of body weight) of glucose was given orally, and venous blood samples were obtained at intervals

of one-half, one, and two hours. The criteria used for the diagnosis of diabetes were those of Mosenthal,[4] i. e., a fasting blood glucose level of more than 100 mg. per 100 ml., a one-hour level of more than 150 mg. per 100 ml., and a two-hour level of more than 100 mg. per 100 ml.

Results

In all, 742 urine specimens from as many individuals were examined. In 30 cases, positive results with one or more techniques were obtained. These 30 persons were recalled, and evaluation was done for diabetes mellitus. The data obtained are summarized in table 1. The first 11 patients are diabetics, with the disease previously unknown in 8. Five patients had borderline glucose tolerance findings and are classified as "doubtful normal." This group has been called prediabetic, latent diabetic, hidden diabetic, or possible diabetic, and such patients should be watched for possible future development of diabetes.[5] Six patients had non-glucose-reducing substances in their urine specimens. Two had renal glycosuria. There were six normal persons.

* Copper sulfate tablet test.
† Glucose oxidase test.
‡ Abnormal glucose tolerance test; details not available (family physician).

A comparison of the results of the tests is shown in table 2. Here it can be seen that diabetes in 2 of the 11 subjects was detected by the glucose oxidase methods but not by the copper sulfate method. Two of the five doubtful normal persons had positive findings in the glucose oxidase tests only. Of the six urine specimens containing non-glucose-reducing substances, positive results were obtained only by the copper sulfate method; none were positive by either of the enzyme methods. One case of renal glycosuria was detected only by the glucose oxidase method. Of the six normal subjects, five showed positive findings in the glucose oxidase method and one in the copper sulfate method.

Thus, of 18 subjects including 11 diabetic persons, 5 doubtful normal persons, and 2 persons with renal glycosuria, negative results were obtained in 5 by the copper sulfate method. Positive results were obtained in all by the glucose oxidase method. Of 12 subjects without diabetes, positive results were obtained by the copper sulfate method in 7 (6 with non-glucose-reducing substances and 1 doubtful normal person). Positive results in the glucose oxidase tests were obtained in five subjects who had normal glucose tolerance findings.

Comment

Screening procedures for diabetes are judged on specificity and sensitivity.[1e] Sensitivity, meaning that a high percentage of persons with the condition should show positive results, was high with the glucose oxidase tests in this survey. In any screening program, it is not possible to know how many subjects actually have diabetes mellitus. Therefore, sensitivity must be estimated by comparing percentage screened who have positive findings in this study with that in other studies. The result of 4% compares favorably with the 86,865 individual examinations collected from several surveys by Wilkerson and co-workers,[1e] in which the average was 2.1%, with a range of 1.3 to 9.0%. In all of these studies a test of blood sugar level was utilized as the screening procedure.

Clinistix alone	0	...	...	...	...	...

* Glucose oxidase test.
† Copper sulfate tablet test.

Of the total group screened, 1.5% had diabetes. This also compares favorably with respect to sensitivity with the collected average percentage of Wilkerson and associates of 0.5% (range, 0.2-2.0%). Another indication of the relatively high sensitivity of the study is shown by the fact that 36% of those screened with positive results had diabetes, which compares favorably with the average of Wilkerson and associates of 24%, with a range of 22 to 64%.

The criterion of specificity, i. e., that a high proportion of persons not having the condition should show negative findings, is fulfilled at least as well by the enzyme tests as by the copper reduction method. According to the diagnostic evaluation, 12 of the 30 subjects with positive results on screening were probably entirely normal. In this group, seven positive results were obtained only with the conventional copper sulfate method and five only with the glucose oxidase tests.

Thus, the glucose oxidase tests were demonstrated to be satisfactory screening methods for diabetes mellitus. Although sensitivity is higher than with the copper sulfate method, the number of false-positive results is no greater; it is considered that the early detection of diabetes mellitus is enhanced by the use of glucose oxidase tests. Since it has been established that transient glycosuria frequently precedes diabetes,[5b] the high sensitivity of the new methods may be of value in detecting persons with doubtful cases of diabetes who should have periodic evaluation.

Summary

Two glucose oxidase tests for glycosuria were compared with a copper reduction method in screening 742 subjects for diabetes mellitus. Of 30 persons with positive findings on the screening tests, 11 had diabetes. The glucose oxidase tests were more sensitive and more specific for glycosuria than the copper sulfate method. The results are comparable to those obtained in surveys where a test of blood sugar level is utilized as the screening procedure.

840 S. Wood (12) (Dr. Chertack).

The copper sulfate tablet test (Clinitest) and one of the glucose oxidase tests (Clinistix) used in this study were supplied by Ames Co., Inc., Elkhart, Ind. The other glucose oxidase test (Tes-Tape) was supplied by Eli Lilly and Company, Indianapolis.

NEW INSTRUMENT FOR BIOPSY OF THE CERVIX AND ENDOCERVIX

Martin H. Chester, M.D., Gardena, Calif.
and
Jesse H. Frank, M.D., Inglewood, Calif.

The perfection of cytological techniques in the detection of early carcinoma of the cervix has necessarily required the widespread use of cervical biopsy for confirmation. The frequent small size of the lesions, their clinically inconspicuous appearance, involvement of the endocervix, and the ease with which they may be destroyed, lost, or rendered undiagnosable by the usual techniques of biopsy have indicated the development of new instruments and methods.

When carcinoma is strongly suggested by cytology but the cervix is clinically free of an obvious lesion, the cold cone is recommended to confirm the diagnosis and define its extent and aggressiveness. However, especially in pregnancy, often reports are given of "cells suspicious of malignancy" or "inconclusive findings," their frequency depending on the competence, self discipline, and philosophy of the cytologist. Here, a less rigorous procedure is permitted, avoiding the disadvantages of hospitalization and the risks of hemorrhage and stenosis. Toward this purpose, a new cervical biopsy instrument termed the Cervicotome is presented. It is designed to obtain tissue specimens from the portio vaginalis, the squamocolumnar junction, and the cervical canal (a "pancervical" biopsy).

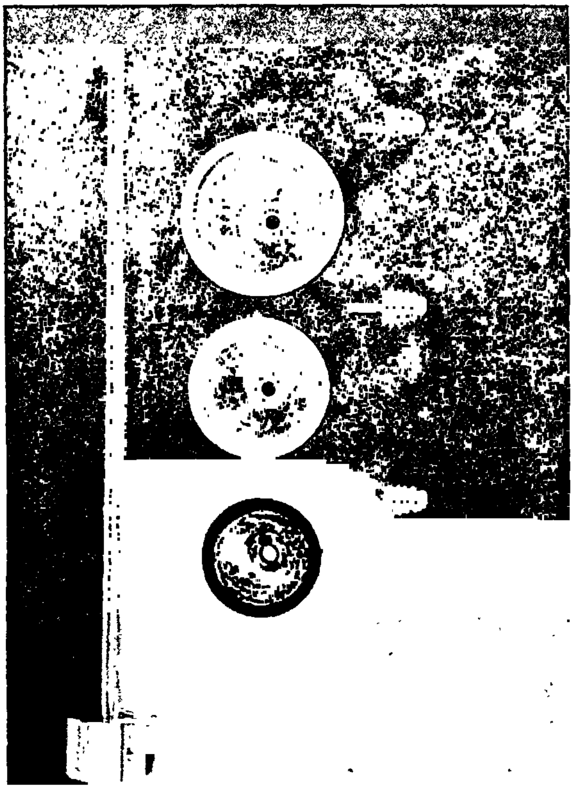

Fig. 1.—Cups, matched blades, and coaxial cutting plug attachments, of several sizes, of biopsy instrument. These are designed to accomodate variations in size of cervix, cervical os, and cervical canal.

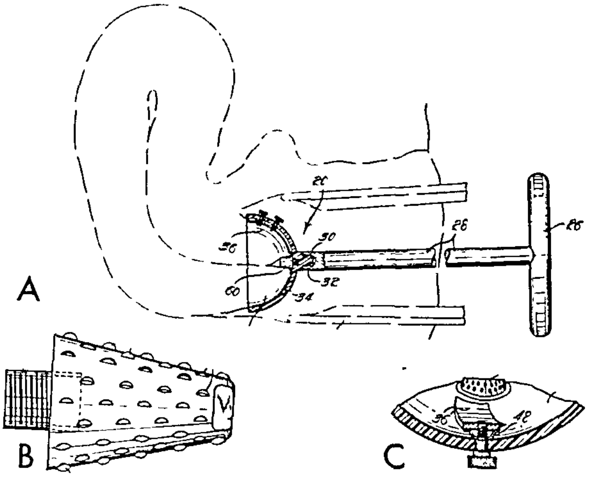

Fig. 2.—*A*, operating position of biopsy instrument, with coaxial cutting plug in cervical canal (60) and cutting blade (36) in contact with cervix. *B*, enlarged drawing of coaxial cutting plug, showing multiple cutting teeth. *C*, detailed drawing of Lucite cup, razor-edged cutting blade (36), and micrometer adjusting screw (48) which determines depth of cut.

This instrument is basically a hemispherical cup attached to an elongate handle. The cup includes an internal curved knife and a coaxial attachment, with multiple serrated cutting edges (fig. 1). The cup and knife are applied over the cervix to remove tissue from part or the entire surface of the cervix, from the external os to a major portion of the portio vaginalis. The concentric cutter will simultaneously obtain small specimens of epithelial and subepithelial tissue from the canal. The cup is made of Lucite to permit the operator to monitor the cutting action.

Operation and Results

With the cervix exposed with a vaginal speculum in place, the Lucite cup is applied to the cervix, with the concentric cutter attachment in the cervical canal (fig. 2). Appropriate pressure is applied to the handle of the instrument as it is rotated in a clockwise direction. Counterpressure may be applied to the fundus with the operator's left hand on the abdomen, at the discretion of the operator. The instrument may be rotated a full 360 degrees where no gross lesions or ulcerations are present on the portio vaginalis.

The instrument may be used in conjunction with Schiller's test and in areas of exophytic growth or gross ulceration. It should be emphasized that the instrument is designed to perform a cutting, rather than a scraping, function. Thus, the physician obtains specimens for definitive histological diagnosis. The specimens obtained from the portio vaginalis and the cervical canal may be examined separately, so that the general location of the lesion will be indicated.

The material obtained is adequate for study, consisting of both squamous epithelial and endocervical tissue and including the junctional zone. The tissue is well preserved, showing less artifact than that obtained by other methods. Necessarily, it is representative of the entire circumference of the cervix, and sufficient lamina propria is obtained to judge infiltration of the stroma.

Summary

A new cervical biopsy instrument, the Cervicotome, is designed to obtain tissue from the portio vaginalis, the squamocolumnar junction, and the cervical canal in one rapid operation. Its use is intended for office practice on ambulant patients, where the cytological diagnosis has been reported doubtful or suspicious, where an infiltrative lesion is probable, or where the patient has refused hospitalization.

16000 S. Vermont Ave. (Dr. Chester).

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for all drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations.

H. D. Kautz, M.D., *Secretary.*

CURRENT STATUS OF THERAPY IN BRONCHIAL ASTHMA

Maurice S. Segal, M.D., Boston

Bronchial asthma is a distressing and common form of acute, recurrent, or chronic bronchial inflammation and obstructive emphysema, usually of allergic origin. The acute paroxysm of bronchial asthma may last for hours or recur in varying degrees of severity for days. Finally, a state of intractable asthma, during which the episode is continuous and refractory to treatment, may result. In this state the patient presents a picture of marked physiological imbalance. Evidence of hypoxia, cyanosis, dehydration, disturbed psyche, peripheral vascular collapse, and further disturbances may be noted because of changes induced by the widespread use of drug therapy. Death is more commonly due to asphyxia resulting from the plugged and obliterated bronchi and bronchioles and from oversedation; it is also due to the failure of endogenous discharge of adrenal hormones necessary in the defense mechanism against stress, and, in more recent years, particularly to steroid sequelae.

Medical Management

The successful management of the patient with chronic bronchial asthma requires a very careful consideration of the responsible factors in bronchial asthma. Such factors include allergic factors (inhalants, ingestants, contactants, injectants), common colds, paranasal sinus disease, bronchitis (allergic, asthmatic), physical factors (seasonal and climatic influences), psychosomatic factors, and miscellaneous factors (exertion, fatigue, endocrine influence, nonspecific pulmonary irritants, infections).

Every attempt should be made to determine the responsible antigens. If a detailed history is inconclusive as to the cause of a patient's bronchial asthma, then scratch testing and intradermal testing may be resorted to. Removal of the offending allergen (allergic cleanliness) and a trial with specific hyposensitization should be promptly instituted in all cases whenever possible. Further therapy should be directed toward removing the contributory factors. Because search for the responsible agents is

---

Clinical Professor of Medicine and Director, Lung Station (Tufts) and Department of Inhalation Therapy, Boston City Hospital.

difficult and often completely unsuccessful, emphasis on the allergic approach to management should not exclude physiological therapy.

Epinephrine.—Epinephrine has been employed in various modifications, concentrations, and routes. Toxic reactions, intolerance, and fastness are more commonly observed with overdosage and repeated parenteral use. Deaths have been reported after intravenous administration. In general, epinephrine given parenterally is limited in its value for the relief of the acute attack. Unfortunately, few physicians or patients limit the dosage to the proper and effective subcutaneous injection of 0.2 to 0.3 cc. of a 1:1,000 dilution of epinephrine hydrochloride. Generally, larger doses at frequent intervals are resorted to, especially when self-administered. The use of the hypodermic needle for self-medication is encouraged too often; the epinephrine-fast state is encountered most commonly in these patients. We have not observed any value from preparations of epinephrine 1:500 in oil.

Most patients in status asthmaticus are epinephrine-fast, and the repeated use of all epinephrine preparations should be avoided until epinephrine sensitivity is restored. We have made a rule of never adding epinephrine to the so-called intravenous cocktail (i. e., intravenous infusion of aminophylline, iodides, dextrose, etc.).

Bronchodilator Aerosols.—Aerosols of sympathomimetic drugs, such as 2.25% racemic epinephrine (Vaponefrin) hydrochloride, isoproterenol (Aludrine, Isuprel) hydrochloride 1:200, a combination of 2.5% racemic epinephrine hydrochloride with 0.5% atropine sulfate (Dylephrin), or a combination of 0.4% isoproterenol sulfate with 2% phenylephrine hydrochloride (Nebu-Prel) have proved to be of great value for the relaxation of bronchospasm. As little as approximately 0.05 to 0.10 cc., nebulized by three to six compressions of a hand bulb, may abort or relieve a mild bronchospastic episode. We have observed clinical and laboratory improvement with administration of these agents.

Recently, epinephrine and isoproterenol have been added to Freons in the form of simple pocket units (Medihaler-Epi and Medihaler-Iso) designed to deliver measured aerosol dosages. The Medihaler-Iso unit is popular with patients and produces improvement in timed vital capacity relationships as tested in those with mild or moderate attacks of bronchial asthma. The class of Freons used to power this has been described as free of toxicity. More recently, a Freon-powered pocket unit has become available with an ingenious reservoir chamber with a self-cleaning, baffling device (Nebu-Halent). This device makes it possible to deliver finer, smaller particle-sized aerosols of bronchodilator agents or other therapeutic aerosols as prescribed by the physician. We were able to determine that in mild paroxysms of bronchial asthma three inhalations with this device, and in moderately severe paroxysms six inhalations, brought effective clinical relief and improvement in timed vital capacity relationships.

More severe bronchospasm may require 0.5 to 1.0 cc. of one of these bronchodilator agents nebulized continuously with oxygen or with the simple Eliot air-pump unit made by the National Cylinder Gas Division of the Chemetron Corp. This treatment generally requires 10 to 15 minutes at a flow rate of four liters per minute.

Aminophylline.—Patients vary in their tolerance to aminophylline. Some become more alert; others become drowsy; many become nauseated and even vomit; and still others complain of palpitation and sweating.

Oral Route: For the prevention of mild but chronic attacks of bronchoconstriction, aminophylline may be given orally, around the clock. The addition of antinausea factors (local and central acting) to aminophylline has made possible the oral administration of larger, effective doses, with or without the addition of ephedrine, iodides, or a barbiturate. A combined preparation containing 300 mg. of aminophylline, 150 mg. of aluminum hydroxide, and 30 mg. of ethyl aminobenzoate (Cardalin), or a preparation containing 200 or 250 mg. of aminophylline, with 15 mg. of ephedrine hydrochloride or 25 mg. of phenobarbital and 15 or 30 mg. of pentobarbital sodium, 150 mg. of aluminum hydroxide, and 15 mg. of ethyl aminobenzoate (Dainite) is most helpful when the dose is carefully tailored for the individual patient's needs and tolerances.

Rectal Route: For more persistent attacks, aminophylline should be administered rectally in doses of 300 to 600 mg. in 15 cc. of tap water every 8 or 12 hours. For children, the dose may be reduced to 60 to 200 mg. The available suppositories are not of equal value.

Intravenous Route: Aminophylline should be given intravenously for severe paroxysms of coughing or wheezing not relieved by epinephrine or bronchodilator aerosols or by aminophylline given rectally. For an attack which has persisted for less than 12 hours, 250 mg. in 10 cc. of water for injection usually brings prompt relief. For a more protracted attack, the dose should be 500 mg. in 200 cc. of water for slow intravenous injection. These infusions may be repeated at intervals of 8 or 12 hours. Syncope and peripheral vascular collapse may be observed if the rate of injection is too rapid (1 cc. per minute is suggested).

For a severe acute attack of bronchial asthma occurring at home, which has failed to respond to self-administered bronchodilator aerosols, epinephrine, sedation, or oral forms of aminophylline, the following routine may be most helpful: 1. A dose of 500 mg. of aminophylline in 20 cc. of solution may be given intravenously. 2. If no lasting relief is observed in half an hour, 0.2 cc. of epinephrine gel (Sus-Phrine) may be given subcutaneously. 3. If no lasting relief is observed in 15 minutes, 75 mg. of meperidine (Demerol) hydrochloride may be given subcutaneously.

If the patient has not previously used adrenergic agents, the order should be reversed to epinephrine gel, aminophylline, and meperidine hydrochloride. The attending physician should move quietly, yet act quickly, with assurance and empathy. The patient who does not respond satisfactorily in one hour's time would benefit most by proper hospitalization.

Continuous Infusion Technique: If intravenous injections of aminophylline become necessary one or more times daily for as long as a week, the continuous infusion technique should be employed. The patient should be hospitalized. A solution is made containing 500 mg. of aminophylline in each liter of 5% dextrose in water. Three liters should be given in 24 hours, with a flow rate of 30 drops per minute. If improvement follows after one or two days of such therapy, the infusions then may be given intermittently, e. g., from 9 a. m. to 9 p. m. daily, reducing the total to 1,500 cc. For the very sick patient, it may be necessary to continue these infusions for as long as 10 days. During convalescence, aminophylline should be given rectally instead of intravenously.

By means of pulmonary function studies, we have demonstrated the presence of latent bronchoconstriction in the patient who has completely recovered. Hence, in these patients, orally given aminophylline in combination with aluminum hydroxide and ethyl aminobenzoate should replace the rectally given aminophylline used during convalescence.

Intermittent Positive Pressure Breathing Therapy.—The use of pressure breathing is based on the creation of a pressure gradient from the mouth down to the pleural space. In the intermittent types, the gas mixture is supplied in the inspiratory cycle, usually through a face mask. There are several effective types of mask apparatus units which supply intermittent positive pressure breathing in inspiration. We have found the Bennett-type cycling valve and the new, extremely sensitive Mark 7 unit most satisfactory for administering positive pressure breathing, especially when combined with inspiratory bronchodilator aerosols. The patient completely controls the cycling of the valve by his own respiratory rhythm. An active inflation of the lungs occurs during inspiration under positive pressure from the cycling valve. The rapid release of pressure at the start of expiration is followed by a high velocity expiratory gas flow. This, combined with the release of bronchoconstriction which follows the simultaneous inhalation of bronchodilator aerosols, promotes better bronchial drainage. We employ pressures of 10 to 15 cm. H_2O with mixtures of air and oxygen. In general, this form of therapy should be reserved for the patient with chronic recurrent attacks who has some degree of complicating ventilatory insufficiency responsible for his disability. It is most useful in reeducation of diaphragmatic breathing and prevention of carbon dioxide retention. We have recently been able to demonstrate actual reduction in mechanical resistance and increase in pulmonary compliance, with resultant lowering of the work of breathing in these patients employing the Mark 7 unit.

In the presence of bronchial infection, bronchiectasis, or tenacious purulent secretions, the use of enzyme aerosols to attack the pus, such as pancreatic dornase (Dornavac), is indicated. It has proved to be efficacious in clearing bronchial infection of a chronic nature. Pancreatic dornase, dissolved in 0.5 or 1 cc. of the bronchodilator aerosol, is administered by aerosol in doses of 50,000 to 100,000 units, one to three times daily for five to seven days, with the continuous aerosol technique or with intermittent positive pressure breathing. It is used in addition to, not instead of, antimicrobial therapy.

Therapeutic Gases.—Oxygen Therapy: If there is hypoxia and cyanosis, the patient should be given oxygen. His physical and personal requirements, as well as the concentration of oxygen desired, should be considered in selecting the type of equipment to be used. Unfortunately, most patients in status asthmaticus tolerate poorly the tight-fitting rubber face masks which are necessary when concentrations of oxygen above 60% are indicated. The simple Eliot plastic face tent supplies average concentrations of 50% oxygen in the inspired air, with oxygen flow rates of six liters per minute. The patients do not complain of claustrophobia or a sense of suffocation.

In general, there has been an overemphasis on the danger of inducing the carbon dioxide intoxication syndrome and respiratory acidosis by the sudden administration of high concentrations of oxygen in patients with classic intractable bronchial asthma. This danger, however, is always present in patients with chronic hypoxia secondary to chronic pulmonary emphysema or chronic pulmonary heart disease, particularly if respiratory depressing drugs are administered before, or along with, the high concentration of oxygen. In these patients the plastic nasal cannula-humidification technique is best employed. Initial low concentrations with flow rates of one liter per minute should be used. The flow rates may be cautiously increased by daily increments to six liters per minute, and subsequently the therapy may be maintained more simply and safely with the Eliot plastic face tent.

Helium-Oxygen Positive Pressure Breathing: If obstructive phenomena predominate, mixtures of 75% helium and 25% oxygen are more beneficial than oxygen alone. Subjective relief of dyspnea and wheezing may be observed frequently after positive pressure breathing of helium-oxygen mixtures. The gas mixture may be administered through the metered mask apparatus (made by the National Cylinder Gas Division of the Chemetron Corp. or by the Oxygen Equipment Manufacturing Corporation) which supplies an expiratory positive pressure when the exhaled air passes through constricted orifices. This method may be tiring, and the patient should be treated for periods of one-half to one hour four times daily. Rebreathing from the collecting bag may be permitted as an economy measure (helium saving). The intermittent positive pressure breathing unit may be employed; it is most efficacious and less tiring for the patient but more costly.

Bronchial Evacuation ("Catharsis").—The bronchitic cough is one of the most troublesome manifestations and may actually serve as the trigger mechanism for more extensive bronchiolar spasm. The therapeutic mechanisms for bronchial evacuation consist mainly in the use of (1) expectorants, (2) iodides, (3) ipecac, (4) positional drainage, and (5) bronchoscopy.

Expectorants: The expectorant drugs may prove quite helpful when properly used. A patient with an effective productive cough should not be oversedated, or the mucus in the bronchioles may become tenacious and inspissated, largely from dehydration and long retention. If the mucus is permitted to become impacted, the cough may become ineffective, and a state of "tussive insufficiency" will develop. One of the antihistamine preparations, a combination of diphenhydramine hydrochloride and aminophylline (Hydryllin) may be of value, particularly in patients with associated vasomotor rhinitis. Among the more ideal expectorants are the iodides, ipecac, and aerosols of water or detergents such as superinone (Alevaire) and Tergitol 08.

Iodides: Iodides are excellent bronchial evacuants. In the very sick patient, 1 to 2 Gm. of sodium iodide may be added to each liter of infusion fluid and administered for several days. When effective productive coughing occurs, the iodides may then be given orally again. Their action results in dilution and liquefaction of the retained secretions. Iodides are more efficacious when the patient is well hydrated. A disagreeable metallic, bitter taste is commonly experienced. The usual precautions in the use of iodides should be observed; namely, close watch for evidence of a variety of rashes and swelling, conjunctivitis, coryza, bronchorrhea, thyroiditis, and adenopathy. Administration should proceed cautiously. The initial dose should be 0.2 cc. of the saturated solution of potassium iodide after each meal and at bedtime. This may be increased by 0.1 cc. per dose each day until a maximum dose of 1.3 cc. is reached. The dose should then be abruptly reduced to 0.2 cc. and the same gradual increase of dosage repeated; this may prevent the development of intolerance. For patients in whom gastric irritation develops from a saturated solution of potassium iodide, enteric-coated tablets are available in 500 mg. and 1 Gm. sizes.

Ipecac: Ipecac acts by substituting effective retching in the place of ineffective coughing. Syrup of ipecac may be administered in doses of two or three teaspoonfuls followed by a cup of lukewarm boiled water. This dose may be repeated several days later, if indicated. It is always worth a trial before bronchoscopy is attempted.

Positional Drainage: Although of little benefit to those with useless cough, positional drainage may be of considerable value to the patient with accumulated secretions that are easily raised. The procedure is generally most efficacious in the management of associated bronchiectasis. It is more effective when carried out after bronchodilator therapy.

Bronchoscopy: One of the most common and important causes of death in asthma is obstruction of the larger and smaller air passages by inspissation of tenacious secretions. At times, spectacular improvement may follow bronchoscopic aspirations, even in a moribund patient. Because of the danger of serious reactions to the use of tetracaine hydrochloride or cocaine sprays and instillations for local anesthesia in asthmatic subjects, we generally prefer deep surgical anesthesia with ether. Intensive bronchoscopic aspiration is followed by marked subjective and objective improvement. It may prevent atelectatic complications, prove lifesaving, and be followed by a long period of remission.

Antitussive Measures.—The most effective antitussive measures center about the prevention of various trigger mechanisms responsible for the coughing paroxysms. Laughter, shouting, talking, crying, inhalation of tobacco smoke, dusts, fumes, fogs, and smogs, sudden changes in temperature and humidity, and exertion are among the leading causes in precipitating troublesome coughing paroxysms, which frequently induce bronchospastic crises, expiratory ball valving, and actual alveolar disintegration. The patient should always be on the alert for these causes, and the sooner he learns his tolerance to these factors the more successful the "cure."

In a recent study in our laboratory we found that benzonatate (Tessalon) was a most helpful agent in the management of pharyngitis and tracheobronchitis. Administered as an aerosol or syrup sipped slowly, this preparation has a pleasing surface-anesthetic effect which, though short-lived, is free of the side-reactions observed with the "caine" preparations. When given orally (in the form of perles), there is suggestive evidence that the antitussive effect occurs by action at the pulmonary parenchymal proprioceptor centers. For more sustained effects in the patient with intractable coughing paroxysms during the daytime, intensive therapy with noscapine (Nectadon), 30 to 60 mg. given orally at graded intervals, has proved quite beneficial. We have not observed respiratory depression, significant drowsiness, or constipation with its repeated use. At bedtime, 15 to 30 mg. of dihydrocodeinone bitartrate has been most beneficial in suppressing the severe nocturnal coughing paroxysms.

Sedation.—Anxiety, fear, insecurity, restlessness, nervousness, insomnia, and mood and personality deviations are commonly encountered in patients with chronic recurrent attacks. These symptoms and a frank "alert state" may be accentuated by the very medications that these patients require, namely, aminophylline, adrenergic compounds, and the corticosteroids.

Heavy sedation should be avoided and only agents with a wide margin of safety used. Sodium bromide or chloral hydrate are helpful for the patient with mild, chronic recurrent attacks. When an attack has persisted for more than several hours, sedation should be given in addition to epinephrine and aminophylline given intravenously.

Meperidine hydrochloride, used in proper dosage, is a useful and safe drug in the treatment of the patient in an acute asthmatic attack or in status asthmaticus when the usual methods of treatment have failed or when fastness to epinephrine or aminophylline has developed. It has a far wider range of safety than morphine. The use of meperidine for a total of two to five days, administered at intervals of six to eight hours orally or parenterally in doses of 50 to 100 mg., has not caused addiction in our patients, even when this course was repeated at intervals of several weeks. However, we do not recommend its routine use in any of these patients. Meperidine can, of course, depress respiration if given in too large a dose or if repeated too frequently in patients with chronic bronchial asthma and associated emphysema.

If meperidine is contraindicated or not well tolerated, a retention enema of paraldehyde (20 to 30 cc.) or ether (60 to 70 cc.) may be administered at intervals of six or eight hours. These have proved of particular value in seriously ill asthmatic patients. Unfortunately, they are often irritating and difficult to retain.

Chlorpromazine (Thorazine), prochlorperazine (Compazine), and meprobamate (Equanil, Meprospan, Miltown) or similar "tranquilizers" may be of considerable clinical value in allaying the anxieties of seriously ill patients. In the hospitalized patient, 50 mg. of chlorpromazine hydrochloride may be administered intramuscularly upon admission and at eight-hour intervals for two to four days. Many patients with marked mood swings, anxiety, and compulsive behavior patterns receive considerable benefit from carefully selected, relatively nontoxic "tranquilizers" when administered over periods of many months. The pepped-up reactions and mood swings noted secondary to corticosteroid therapy have also been allayed in many patients with the simple addition of meprobamate plus prednisolone (Meprolone).

Management of Infections.—Evidence of respiratory tract infection is present in most patients with intractable bronchial asthma. Study of the sputum usually reveals polymorphonuclear leukocytes, bacteria, or pus in these patients. The leukocyte count, polymorphonuclear counts, and sedimentation rate may also be elevated. In general, the choice of the antimicrobial agent depends upon the predominating organisms, their drug susceptibility, and the patient's tolerance for the drug itself. Perceptive clinical judgment, tempered by practical bacteriological observations, is necessary in deciding what drugs or combination of drugs and dosages should be employed in an attempt to suppress the total infection. Complete eradication occurs rarely.

Although the clinical activity of penicillin is entirely confined to infections caused by gram-positive micro-organisms, it is the most useful agent in these patients. Unfortunately, the high incidence of local or generalized allergic reactions to penicillin aerosol in these patients limits this technique, which is otherwise most useful for the management of chronic bronchial infections. Penicillin is of particular value for hemolytic streptococci, since one does not usually encounter resistance. Unfortunately, an increasing number of strains of hemolytic staphylococci are penicillin-resistant. In these instances, erythromycin (Ilotycin), novobiocin (Albamycin, Cathomycin), kanamycin (Kantrex) sulfate, or chloramphenicol (Chloromycetin) should be administered. Because of the finding of mixed gram-positive and gram-negative organisms in most of our hospitalized patients seriously ill with intractable bronchial asthma and respiratory tract infections, we have administered combinations of 300,000 units of procaine penicillin G and 500 mg. of streptomycin sulfate every 12 hours. These combinations should be employed only for three to seven days because of the development of resistance to streptomycin in numerous instances. The incidence of severe reactions to penicillin given parenterally in patients with chronic bronchial asthma is higher than in the general hospital population, and a careful history of previous experiences with this drug should be elicited.

As an alternative or as a primary choice, one of the broad-spectrum antimicrobial agents—oxytetracycline (Terramycin), chlortetracycline (Aureomycin), tetracycline (Achromycin, Panmycin, Polycycline, Tetracyn), or chloramphenicol—may be used. In seriously ill patients, dosages of 250 mg., administered at six-hour intervals during the meal or with a glass of milk, may be employed for several days. The dosages should be tapered downward as soon as possible. Evidence of proctitis, Monilia invaders, granulocytopenia (with use of chloramphenicol), complicating Proteus vulgaris organisms, pseudomonas infections, and idiosyncrasy should always be looked for. The addition of nystatin (Mycostatin) when fungi appear in the sputum is advisable.

Confronted with the problem of an overwhelming bilateral pneumonia in a patient with intractable bronchial asthma which is not responsive to a host of antimicrobial agents, the physician is justified in adding corticotropin (Acth, Acthar, Corticotropin) or soluble hydrocortisone sodium succinate (Solu-Cortef).

Prophylactic antimicrobial therapy is of considerable value in debilitated patients with intractable bronchitis and asthma who are subject to recurrent respiratory tract infections during the winter months. In general, we employ orally one of the following antibiotics in the stated dosages: 500 mg. of sulfadiazine, 100,000 units of penicillin, or 100 mg. of tetracycline, given every 12 hours. These doses occasionally require slight revision.

It should always be kept in mind that to suppress or eradicate bronchial infection it is not sufficient to convert a purulent sputum to a mucoid one. The sputum must be adequately evacuated by employing the aforementioned principles of bronchial evacuation, with the use of positional drainage, expectorants, bronchodilator aerosols, pressure breathing therapy, and bronchoscopy.

An irreparable sinobronchitic syndrome often follows in the wake of chronic paranasal sinus disease. Free drainage of the paranasal sinuses and elimination of infection should be attempted. Allergy appears to be the dominant factor in most patients. The topical use of the "safer" vasoconstrictor drugs, such as phenylephrine hydrochloride in combination with an antihistaminic, corticosteroid, and antibiotic agent, is of considerable aid in maintaining nasal patency and limiting infection. With evidence of frank purulent infection, 100,000 units of potassium or sodium penicillin G may be added to 1 cc. of 1% phenylephrine hydrochloride and administered with the Eliot air pump unit employing nebulizer and nasal tips. Treatments can be given at intervals of four to six hours for days or weeks, as indicated and tolerated.

Remissive Measures.—The use of adrenal steroid therapy should represent but a single phase, albeit important, in the total therapeutic program. Although these hormones frequently have a striking ameliorative, anti-inflammatory, and antiallergic clinical effect (antiphlogistic), they seem only to arrest the disease and usually do not suppress it. They should be employed for restricted and considered use when all other conventional methods of therapy have proved ineffective in securing a remission. Unfortunately, in the management of the patient with chronic bronchial asthma, the physician pushing steroid therapy may find himself like the man holding the tiger's tail because of the problems attendant to withdrawal therapy.

Changes During and After Hormone Therapy: Accumulation of eight years' clinical experience and extensive laboratory studies with these hormones have resulted in recognition of the many side-effects and toxic reactions as well as an appreciation of the precautions and contraindications to be observed. The undesirable effects that may follow the clinical use of hormones may be classified generally into two groups, those caused by overdosage and those caused by withdrawal of the hormone. Since successful steroid therapy depends upon a state of hormone overdosage, it is unavoidable that effective hormone therapy will be associated with an exaggeration of the patient's normal physiological actions. Any of the symptoms and finally the full-blown picture of adrenocortical hyperfunction (Cushing's syndrome) may develop. In particular, diabetes mellitus, gastrointestinal hemorrhage, hypertension, osteoporosis, and growth arrest in children should be closely watched for.

Symptoms of hormone withdrawal are the result of a state of adrenal-insufficiency created by hormonal suppression of adrenocortical function. The symptoms may be mild or severe, depending upon the dosages employed, duration of therapy, and rate of withdrawal of the hormone. This state of relative adrenal insufficiency may resemble the course of adrenal cortical hypofunction (Addison's disease). Any additional stress in the form of trauma, shock, surgery, or severe infection during this state of insufficiency may prove disastrous to the patient.

On decreasing the dose during withdrawal of the hormones, aches and pains, lassitude, and a wide spectrum of personality changes may occur. These symptoms usually clear up when the dose is increased but may recur when another attempt is made to decrease the dose. A delicate balance must be found with each patient.

The wide varieties of changes noted during and subsequent to steroid therapy are listed as follows. The less serious changes include facial mooning, acne, petechiae, purpura, edema, hirsutism, skin pigmentation, increased appetite, insomnia, headaches, aches, pains, weakness, lassitude, euphoria to mild depression, mental and physical hyperactivity, hypertension, tachycardia, glycosuria, hyperglycemia, aggravation of existing diabetes, depressed thyroid function, thrombophlebitis, and sensitivity reactions to corticotropin given intramuscularly, such as skin rashes, pruritus, urticaria, occasional wheezing, and angioneurotic edema. The more serious changes include potassium deficiency, muscular weakness, negative nitrogen balance, osteoporosis and fractures, especially in women after menopause and in immobilized patients, masked infections (bacterial, viral, and fungal), spread of existing infections, serious spread of nonpathogenic inhabitants of the gastrointestinal and respiratory tracts, mental confusion to severe psychotic manifestations, convulsions, exacerbation of quiescent ulcers, gastrointestinal hemorrhage and perforation, activation and spread of unsuspected or inactive tuberculosis, sensitivity reaction (anaphylactic shock), periarteritis, and postoperative adrenal insufficiency. The most serious or fatal changes include the withdrawal syndrome, "adrenocortical storm," poor tolerance to trauma, shock, and infections, and active atrophy of adrenal cortices.

Therapeutic Precautions: Among the therapeutic precautions to be followed are restriction of sodium chloride in the diet to 750 mg. daily, with corticotropin, cortisone (Cortisone, Cortogen, Cortone) acetate and hydrocortisone (Cortef, Cortril, Hycortole, Hydrocortone) therapy. The newer corticoid analogues do not usually require this strict restriction. The occasional use of chlorothiazide (Diuril) may be helpful when indicated by the presence of hypertension and/or the excessive weight gain from fluid and salt retention. Potassium may be routinely administered in the form of a tableted mixture containing 500 mg. of ammonium chloride and 500 mg. of potassium chloride (Pot-Amide), 8 tablets daily. Supplemental potassium in the form of orange or cranberry juice (8 to 12 oz. daily) is preferred by many patients. The supplementary ammonium chloride in the Pot-Amide preparation acts as a mild diuretic agent and is followed by excretion of sodium and water. Potassium replacement is best carried out when the salt-retaining type of steroids is employed. This is of particular value in patients with moon-face, fluid and salt retention, and weight gain syndrome. In the presence of infection or suspected infection, the concomitant use of an antimicrobial is advisable. In general, the patient should receive a high-protein diet to offset the tendency toward negative nitrogen balance. For patients with a tendency toward gastric hyperacidity, it is advisable to prescribe antacids and belladonna alkaloids during hormone therapy. Periodic guaiac tests of finger specimens of stool are advisable in these patients and in others suspected of having gastrointestinal ulceration. When in doubt, a series of x-rays should be taken as a control measure. The use of androgens and/or estrogens is perhaps indicated when the patient receiving hormone therapy has evidence of osteoporosis, noted more usually in patients over 50 years of age who are on long-term therapy. Patients should receive adequate supplemental doses of corticosteroids in case of surgery, severe trauma, or other forms of major stress. To minimize adrenal suppression and atrophy in patients receiving long-term therapy with the corticoids, corticotropin gel may be administered periodically, and particularly when corticoid withdrawal is started.

Hormones.—Hormonal therapy should not be used until all of the other measures which may be indicated have been adequately employed. Finally, hormonal therapy is best employed in conjunction with the foregoing measures to secure a more effective and lasting remission, with the lowest possible dosage schedule and freedom from side-reactions. In patients with severe seasonal (pollen) asthma, short-term therapy should be administered when the patient has failed to respond within a week to intensive antihistaminic and bronchodilator therapy started at the very outset of symptoms.

Oral Route: The following corticosteroids have been used orally in order of their development: cortisone, hydrocortisone, prednisone (Deltasone, Deltra, Meticorten), prednisolone (Delta Cortef, Hydeltra, Meticortelone), methylprednisolone (Medrol), triamcinolone (Aristocort, Kenacort), and more recently, dexamethasone (Decadron, Deronil). In general, it has been our custom to consistently employ lower initial therapeutic and maintenance dosages and to withdraw the drug with smaller reductions and over a longer period of time than reported by other investigators. This is possible when intensive supplemental, physiologically directed therapy is carried out simultaneously. It is our belief that fewer significant side-reactions will then be observed. Nevertheless, a continuous high index of suspicion of the hazards previously listed must be maintained at all times. This applies to all corticoid analogues, regardless of their purported safety features.

We have observed considerable variations in individual responses to the steroids. On occasion, a patient not responsive to prednisolone has shown dramatic improvement with cortisone or hydrocortisone. Similar observations may be noted with the newer prednisolone analogues triamcinolone and dexamethasone. The physician should be prepared to change preparations from time to time. The advantages of less profound alteration in potassium depletion and sodium retention, in the face of adequate anti-inflammatory properties, and the ability to select the agent best suited for the individual patient's appetite needs have given these newer corticoid analogues a more desirable status for general use than the parent compounds, cortisone and hydrocortisone.

During the seasonal (pollen) bouts of bronchial asthma, steroid therapy should be employed on a short-term basis only when the more conservative physiological measures have failed. Therapy over the shortest period of time commensurate with the patient's pollen season is usually adequate. The patient with tree, grass, and ragweed pollen asthma may not require therapy during the entire period from spring to Labor Day. Individual variations in sensitivity to different pollens may be elicited in careful history taking of previous years. The patient with ragweed pollen asthma is particularly grateful.

For the patient with chronic, intractable bronchial asthma, when vigorous therapy has failed, long-term steroid therapy becomes necessary. The physician does well to be "reluctantly forced into therapy" rather than to start it at once. He should not be motivated by the desire to show the patient, his family, and friends a brilliant therapeutic result by first starting steroid therapy.

During the past three years we have observed the effects of prednisolone in more than 400 adult patients with various types of chronic bronchial asthma and associated allergies. The dosage schedule most commonly followed was 5 mg. four times daily for the first three days, 5 mg. three times daily for four days, 5 mg. twice daily for seven days, and 5 mg. or less daily thereafter. Approximately 10% of the patients were able to remain on maintenance doses of 2.5 mg. Another 10% required slightly higher revisions initially and for maintenance. The majority of the patients were maintained on 5 mg. daily. During periods of unexplained stress or infections, the patients were permitted to return to their initial starting schedule, followed by the same gradual reduction. The reduction in dosage for withdrawal from long-term therapy is presently advised at 1 mg. per month. The drug may ultimately be spaced at intervals of two or three days during withdrawal. Preparation for surgical procedures is accomplished by returning to the full initial schedule two days before surgery. At times, supplemental hydrocortisone sodium succinate therapy given intravenously on the day of and after surgery is advisable.

With the use of prednisolone-meprobamate, we have not observed any over-all reduction in the basic dosage requirements. However, many patients with steroid-alert manifestations and patients during the pollen season appear to prefer this combination. It was considered best to maintain patients, with a past history of gastrointestinal bleeding, on buffered prednisolone (Co-Hydeltra). Supplemental antacid therapy is often advisable.

We recently reported on our observations in 44 patients with chronic bronchial asthma and allied disorders who were treated with triamcinolone. An additional 32 patients with chronic bronchial asthma have been studied since this report. There appeared to be a greater weight loss in this series than in the series who were given prednisolone. The over-all results were good; facial mooning and weight gain in some patients, but no serious sequelae, were observed. We have not observed any anorexia, weakness, or clinical evidence of excessive nitrogen or potassium loss in our patients with chronic bronchial asthma. The dosage requirements were on the order of 4 mg. of triamcinolone to 5 mg. of prednisolone (4:5). The schedules previously described for prednisolone were followed.

At the present time, we have under observation 52 patients with intractable bronchial asthma being treated with dexamethasone. This is an unusually interesting new steroid agent; more than one-half of the patients have noted tremendous increase in appetite and consistent weight gain. The weight gain has been influenced but little with supplemental chlorothiazide. However, there appears to be a greater incidence of bleeding from the gastrointestinal tract thus far in our observations. Two patients developed bleeding; one had no history of peptic ulcer, whereas the other gave a history of duodenal ulcer. Dexamethasone appears better suited for the debilitated patient in whom weight gain is important. The dosage of this agent required for suppression of asthma is in the ratio of 1:3, as compared with that of triamcinolone.

Intravenous Route: The intravenous route is more efficacious for the hospitalized patient in serious status asthmaticus. The patient is started on a continuous infusion of 5% dextrose injection, 30 drops per minute flow, thus ensuring approximately three liters per 24 hours. Aminophylline, 250 to 500 mg., is added to each liter, depending upon the patient's responses and tolerance. For the patient who has not received steroid therapy recently, 10 mg. of corticotropin is added to each liter, and a total dose of 30 mg. per 24 hours is given for one to three days. Those who have been on corticosteroids should receive hydrocortisone or hydrocortisone sodium succinate given intravenously. The quantitative eosinophils, which are consistently elevated at the outset, are usually low or absent by the second day of this program. With improvement in the patient, the corticotropin is administered only in the first liter of fluid daily for several more days. In the most severe cases, the infusion of dextrose and aminophylline is continued for an additional one or more days. With intravenous therapy the immediate results are generally more striking. However, the physiological hazards, particularly disturbances in psyche, potassium imbalance, and facial mooning, may be more pronounced.

Attempts should be made to maintain the remissive state with the use of aminophylline solution given rectally or oral preparations of aminophylline and bronchodilator sprays, given as needed. During treatment and after remission, many patients note that they can "do more with considerably less" of their therapeutic armamentarium.

Surgical Management

The proper management of the patient with chronic recurring bronchial asthma may tax the character and ingenuity of the physician. The therapeutic problem may be made even more difficult by the family and the disturbed emotional make-up of the patient. The physician should acquire a proper attitude of empathy rather than overt sympathy, and he should strive to firmly adjust the patient's personality to his disease. A mutuality of confidence must be established. Every severe asthmatic episode should be carefully considered apart from previous seizures. The "whims and cure-alls" of his patient and family should not be curtly dismissed but discussed rationally.

Unfortunately, too often, as with many chronic diseases, the hope of "surgical cures" is brought up. Benefit has been described after a wide variety of surgical procedures, and, indeed, specificity has been "suggested" for these measures. Notwithstanding the great technical skill of the modern thoracic surgical team, there appears but little enthusiasm for the operative procedures designed for the purpose of influencing the neurogenic control of the bronchioles and chemical secretions. Unfortunately, observations made in the laboratory on cats and dogs cannot be translated accurately into changes to be observed in humans with chronic bronchial asthma. Occasionally, brilliant temporary results have been reported after procedures attacking the sympathetic or parasympathetic (vagal) or both systems. These procedures have varied from the simpler procedures designed to block vagal influences, such as procaine injection to the vagal fibers in the mastoid region and procaine or alcohol block of the sympathetic stellate ganglions and the upper four thoracic ganglions, through a variety of unilateral and bilateral cervicothoracic sympatholytic or parasympatholytic designed resections. Finally, bilateral resection (two stages) of the posterior pulmonary plexus as well as resection of cervicothoracic sympathetic and complete pulmonary plexectomies have been performed. No unanimity of opinion as to the ideal surgical procedure for these hapless patients can be found. In fact, most of the early enthusiastic surgical investigators have stopped their search for surgical surcease. Many patients improve temporarily after these procedures. Long periods of rest in the hospital and intensive medical care may well explain this. The physiological and financial stress of major surgery, the attendant pain and discomfort, the complications of pneumothorax with ganglion surgery, trauma to bronchi and blood supply, with intrathoracic procedures and the discomfort of residual, unilateral, or bilateral Horner's syndrome and skin temperature changes noted after sympathetic surgery (the patient "looking and acting like a sad St. Bernard Dog") are quite disconcerting to say the least.

There is still another surgical procedure which has found some favor among thoracic surgeons. Beneficial results have been described in patients in whom excision of "trigger areas" of pulmonary destruction (bronchiectasis) or excision of areas of large emphysematous bullae was carried out. Excisional surgery, along with some type of interruption of the upper sympathetic or parasympathetic vagal chain below the level of the recurrent laryngeal nerve, is usually advocated by these surgeons. Definite bronchiectatic disease (saccular), which is unequivocally demonstrable (after maximal bronchodilation) by radiography and bronchography and which has served as a nidus for recurring pneumonitis, chronic suppurative disease, pulmonary hemorrhage, or progressive debility, should be dealt with as bronchiectasis per se and not as a possible "trigger mechanism" for chronic bronchial asthma. The indications for resectional surgery in these patients are clear-cut and uniformly accepted, and the curative results from the effects of the bronchiectasis are excellent. However, the course of the associated chronic bronchial asthma is usually not affected for long. The segmental bronchial areas, suggesting cylindrical bronchiectasis by radiography or bronchography, should not be resected unless the well-defined criteria referred to previously for resection of a proved saccular bronchiectatic area are present. After resection, lasting improvement should not be expected in the associated chronic bronchial asthma.

Similar criteria should be applied to the patient with chronic bronchial asthma, secondary chronic pulmonary emphysema, and large bullae (seldom seen in this order of relationship). Demonstration of a progressive space-occupying lesion, which is encroaching on functioning lung, an expiratory check-value mechanism, and repeated bronchopulmonary infections with laboratory evidence of ventilatory insufficiency despite adequate therapy, is an indication for surgical intervention in patients with large bullae associated with chronic pulmonary emphysema and secondary bronchospastic crises. The choice of plication, excisional procedure, or another type of tailoring operation should be individualized.

The author has a dim view of the present status of the aforementioned thoracic surgical procedures for the cure or amelioration of chronic bronchial asthma. After surgery these patients generally continue to require long-term intensive medical therapy. Fortunately, physical rehabilitation and the use of adrenal steroid therapy, particularly with the newer corticoid analogues with potentially less mineralocorticoid reactions, intensive bronchodilation, and antibiotic therapy, have made their care more pleasant. Nevertheless, more adequate management of this large group of "pulmonary cripples" continues to remain a challenge to the family physician and the specialist. Unfortunately, these patients all too frequently require an "economic prescription."

The dexamethasone used in this study was supplied as Decadron by Dr. Elmer Alpert of Merck, Sharp & Dohme Research Laboratories, Division of Merck & Co., Inc., Rahway, N. J.

COUNCIL ON INDUSTRIAL HEALTH

THE LEGAL SCOPE OF INDUSTRIAL NURSING PRACTICE

This report has been prepared by the Committee on Industrial Nursing of the Council on Industrial Health, American Medical Association, in collaboration with the Association's Legal Division.

B. Dixon Holland, M.D., *Secretary,*
Council on Industrial Health

The purpose of this report is to discuss the legal scope of the practice of industrial nursing and the functions which a professional industrial nurse may legally perform. The intensification of the educational program of nursing, the increased dependence of the physician on the skills and discretion of the nurse, and the ability of the nurse to meet the challenge of an ever-rising standard of patient care have motivated the nursing profession to define and seek recognition for those professional functions which the nurse performs independently. This is especially true of the industrial nurse who often works without immediate medical supervision.

The Practice of Nursing

Nursing and medical practice are interrelated and frequently indistinguishable from each other. The same act may be clearly the practice of medicine when performed by a physician and likewise a practice of nursing, depending on the circumstances, when performed by a nurse.

There are, of course, limitations on the functions which the nurse may perform, whether independently or under the supervision of a physician, and there are likewise limitations on the functions which may be legally assigned by a physician to a nurse. These will be discussed in this report.

The statutes of the various states which define professional nursing are too nebulous to provide a usable guide in determining the functions in which a nurse may legally engage. Essentially the statutes define professional nursing as involving the carrying out of treatment prescribed by a licensed physician and the application of nursing skills. Obviously, such definitions do not identify the particular functions in which a professional nurse may engage.

Probably the lawmakers should be commended for their foresight rather than criticized for ambiguity. A half-century ago when the first nursing practice acts were adopted the principle function of the nurse was to aid the physician by performing tasks under his direction. The functions of nursing are constantly expanding, and precisely drawn statutory definitions of the functions of nursing could not be kept up to date with changes in professional practices. However, the growing body of judicial decisions reflects the development of the profession of nursing and its expanding responsibilities in the wake of medical progress. The identification of particular functions as nursing functions and the standards of competence required of professional nurses in executing these functions have undergone a rapid and continuous process of evolution among those who are professionally responsible for the care of the sick and injured.

Courts have held that professional nurses have a legal duty to interpret evidence presented by the patient possibly indicating the need for medical attention, and to proceed in the light of that interpretation to do what is required for the patient, as for example the need to call a physician [1]; to discontinue a treatment where there is evidence of its harmful effect, e. g., on an unconscious patient [2]; or to determine the patient's need for special medication, e. g., sedatives.[3] There can be little doubt that by custom and usage the relationship between doctor, patient, and nurse is one in which the parties recognize that the nurse as well as the physician has the function and responsibility to observe and interpret the patient's reactions.

The observation of symptoms and the making of a diagnosis imply the need for professional learning and mental acuteness. These functions are characteristic of the professional nature of nursing as well as medicine. The industrial nurse who observes the extent of illness or injury to an injured workman and determines whether she should render emergency treatment or wait until the physician arrives has made a vital diagnosis comparable in importance to many of those which physicians are called on to make. However, except for first-aid treatment and the employment of such measures as will prevent aggravation of the patient's

Lamb, M.D., Indianapolis; Katherine A. Lembright, R.N., New York; O. Tod Mallery Jr., M.D., Wausau, Wis.; Charles F. Shook, M.D., Toledo; Sara P. Wagner, R.N., New York. The consultant from the Legal Division is Mr. Bernard Hirsh, Chicago.

injury or illness, the determination of therapy is within the exclusive domain of medical practice and beyond the limits of nursing practice.

Nurse's Malpractice

In *Cooper v. National Motor Bearing Co.*[4] the defendant appealed from a judgment in favor of the plaintiff in a malpractice action brought against a registered nurse and her employer.

In May, 1951, the plaintiff received a puncture wound on his forehead when another employee let a piece of metal slip from his hand. He went directly to the first-aid room and received treatment from the defendant nurse. She swabbed the wound with an antiseptic and put a bandage on it. According to the plaintiff's testimony she did not examine or probe the wound. He was told to return the next day which he did. The nurse again applied antiseptic but did not probe the wound. On the next day he also went to the dispensary, but on that occasion the nurse just looked at the wound.

On visits to the dispensary over a period of several months the plaintiff would point out to the nurse that the wound did not seem to be healing properly and she would say that if it did not she would have to do something. In March, 1952, the plaintiff visited the dispensary for a check of a chest injury and asked the nurse if she would send him to a doctor to examine his forehead. She referred him to a physician who excised a piece of tissue for laboratory examination. A pathologist examined the specimen and reported that it contained a basal cell carcinoma. On March 23, 1952, the plaintiff was operated on and a larger area was excised. Skin was removed from his right forearm and grafted to the forehead.

The plaintiff's case was tried on the theory that a metal splinter was left in the wound by the negligence of the nurse and that this foreign body, acting as an irritant, caused the cancer.

The nurse admitted that it was her duty to refer any condition or injury she was not familiar with, or sure about, to a doctor for diagnosis. The standard of good nursing care in the community required the nurse to examine the wound for foreign bodies. If splinters were too deeply embedded, the nurse was to send the workman to the doctor. The plaintiff's type of wound should normally have healed in about a week. If a wound persisted and did not heal, proper nursing care would require that the workman be sent to the doctor. The nurse admitted that she was familiar with the danger signals of cancer, one of which is "any sore that does not heal." Nevertheless she continued to treat the wound for 10 months before sending the plaintiff to the doctor.

In affirming the judgment of the trial court, the California District Court of Appeal said:

> a nurse's diagnosis of a condition must meet the standard of learning, skill and care, to which nurses practicing that profession in the community are held. A nurse in order to administer first aid properly and effectively must make a sufficient diagnosis to enable her to apply the appropriate remedy. Usually she receives some history of the accident or illness from the patient, inspects a wound, and bases her choice of treatment on the deductions thus made. She has been trained, but to a lesser degree than a physician, in the recognition of the symptoms of diseases and injuries. She should be able to diagnose, according to appellant nurse's own testimony herein, sufficiently to know whether it is a condition within her authority to treat as a first aid case or whether it bears danger signs that should warn her to send the patient to a physician . . .
>
> Appellant nurse testified that it was the practice of a nurse in this type of industry to probe wounds for foreign bodies, that if there is a foreign body in a wound there is a feeling of sharpness on pressure, that according to the standard of care and her experience as a nurse, she should be aware of the possibility of foreign objects in such a wound.

If the plaintiff's cancer was the result of the nurse's failure to refer him to a physician for examination and treatment during the 10-month period during which she treated him, then it must be acknowledged that a judgment based on malpractice was proper. Employees as well as their employers are responsible for damages due to acts of negligence.

In other than emergency cases where a physician is not present, diagnosis is not a function of professional nursing and treatment by nurses is generally restricted to the execution of orders given by and under the direction or supervision of a physician. Furthermore, the nurse should only execute legally valid medical orders which she is qualified by training and experience to perform.

Nursing Functions

It is axiomatic that the practice of medicine may not be delegated to nonphysicians. Nevertheless there are numerous traditionally medical functions which are now also performed by nurses under the supervision or direction of a physician and recognized to be nursing functions. Accordingly, under the direction or supervision of a physician, a nurse may administer injections intravenously[5] or intramuscularly[6] or perform x-ray treatments.[7]

Basal metabolism tests, anticoagulant therapy, and the administration of blood transfusions and oxygen are now routinely performed by nurses. The great progress in the science of medicine has led to the delegation of numerous medical procedures to nurses. The first-aid equipment used by the industrial nurse today could have been used only by a physician not too many years ago.

On the other hand the order of a physician purporting to delegate to a nurse the authority to perform an abdominal operation, or an amputation, or to set a fracture or to perform any similar procedure would undoubtedly be considered invalid by the medical and nursing professions as well as the courts. In realistic terms, professional nursing practice includes not only emergency diagnosis and treatment but those medical acts and techniques which are commonly performed by qualified nurses under physicians' orders. Fundamentally, the scope of nursing practice is determined by medical custom. None of the statutes relating to nursing practice attempts to set forth the specific functions of nursing. This statutory flexibility has allowed for the rapid growth of nursing. Consequently the courts have been guided in identifying nursing functions by customs and practices of the medical profession, since physicians can best recognize the proficiency and attainments of nurses.

Emergency Treatment

A medical emergency may be defined as an unforeseen illness or injury which calls for immediate action for the safety of the patient.[8] Anyone, and not necessarily a professional nurse or a physician, may render first aid or perform medical acts to preserve life and limb in the case of an emergency. But one who renders aid in an emergency is under a legal duty to act as a reasonably prudent person. The qualified industrial nurse would generally be held to a greater degree of responsibility and skill than the layman, but to a lesser degree of responsibility than the physician.

Medical custom has permitted a broad definition of the term "emergency" to be applied. It ordinarily refers to situations requiring resuscitative or other first-aid measures. Guiding principles and procedures, approved by a responsible physician, are particularly useful to industrial nurses in such cases.

The case of *Burns v. Bakelite Corp.*[9] is a landmark court decision in the field of industrial nursing. It states the rule that an employer has a duty to provide emergency medical care and other assistance when an employee suffers a sudden illness while engaged in work. The court found that a registered nurse, acting on behalf of the employer, fulfilled this duty but many physicians and nurses may feel that the nursing profession is capable of maintaining a higher standard of performance than that demanded by this court. Because of its basic importance and interest, the holding and facts of the case are stated below in detail.

The plaintiff, who incidentally happened to be a trained nurse, alleged that the negligence of a registered nurse employed by the defendant was responsible for the death of her husband. The trial court judge before whom the case was tried took the case from the jury and rendered judgment himself for the defendant. In a jury case the trial judge is justified in doing this only "if fair-minded men could not differ" in their judgment.

The nurse, Mrs. B——, testified that on a certain morning the plaintiff, Burns, came to the dispensary, pale and perspiring, and she thought he looked ill. He complained of a severe chest pain and thought he had indigestion and he wanted peppermint for it. The nurse took his pulse and his temperature, and found both were normal. He had no difficulty in walking. The nurse suggested he see a doctor, but he refused to see the plant doctor whose office was only about two blocks away, and he asked for his own physician. The nurse tried unsuccessfully to reach the physician by telephone. Then the plaintiff asked her to send him home, and she summoned a car, a station wagon. Refusing assistance, he walked to the car and got in. By the removal of one of the station wagon seats, room could have been made for a stretcher, but the plaintiff was not put on a stretcher.

He was driven by the company's chauffeur to his home. The house was 50 ft. from the roadway, and to reach the front door it was necessary to mount seven steps. The chauffeur opened the door for the plaintiff and he got out and without aid walked to the house and climbed the stairs.

The nurse contacted the plaintiff's doctor soon after the plaintiff had left the plant but he was engaged in an operation and sent a colleague. The doctor gave a diagnosis of coronary occlusion. He was taken to a hospital where, six days later, he died. The opinion of the court states:

> Generally, no duty rests on an employer to provide medical service or care for an ill or injured employee. Yet when the employee, while engaged in the work of his master, suffers a sudden illness that renders him unable to provide for his own care, the employer must put in his reach such medical care and other assistance as the emergency thus created may in reason require. The duty arises out of necessity. . . .
>
> The symptoms that the nurse observed were typical of the onset of a heart attack, although they might indicate acute indigestion or some other condition. But a physician would probably have made a tentative diagnosis of a "coronary occlusion" because that is the most common cause of such symptoms. Based on that diagnosis, the standard emergency treatment would have been the administration of morphine to relieve the pain, not only for the patient's immediate ease but because the pain causes reactions in the heart that increase the damage to that vital organ. And the patient should not be permitted to walk or to make avoidable physical effort. But Mrs. B—— is not a physician; she did not realize that Burns was suffering from a coronary thrombosis; she only knew he was ill and he did not appear to her to be seriously ill. Even if the nurse had made a diagnosis of heart attack, she was not authorized to administer morphine, for such drugs are administered only after the direction of a licensed physician. . . .
>
> There is no negligence indicated by Mrs. B——'s failure to recognize the particular ailment from which Burns was suffering. But should the various symptoms that she observed and that we have recited have warned her it was dangerous to allow Burns to be taken home in the station wagon? If so, there was a failure to exercise due care. If fair-minded men, after carefully considering the facts, could differ in their answer, then the question should have been left to the jury. . . . Run over the facts again—face pale, perspiring, severe pain in chest, pulse and temperature normal, walked without difficulty; the man himself thought he had indigestion; the nurse thought he looked ill, but not very ill. In our opinion, there

> was nothing to suggest that he was a stretcher case, or that there was need for other means than those employed, or for more care than was exercised in sending decedent home. We find no error in the award of judgment to defendant.

The significance of the case is that it recognizes the duty of the industrial nurse to make a tentative diagnosis of the patient's condition. The nurse was not held to the standards of diagnosis required of a physician, although the court felt that the symptoms were such that a physician would probably have made a tentative diagnosis of a heart attack. Actually, many industrial nurses would probably have suspected the symptoms in the case as common symptoms of a heart attack.

Summary

The profession of nursing is a dynamic discipline which embraces an ever-increasing number of functions. Nurses, particularly those employed in industry, should be careful to limit their diagnostic and therapeutic activities to emergencies and to avoid continued treatment of a patient unless such treatment involves the carrying out of the specific orders of a physician who is in charge of the case.

Under the direction or supervision of physicians, nurses are performing as nursing practice numerous procedures which were formerly performed exclusively by physicians. The limitations on the procedures which a nurse may properly perform are governed by (*a*) the nature of the relationship between the medical and nursing professions in the community, (*b*) the scope of training offered in recognized nurses' training schools, and (*c*) the training, experience, and proficiency of the individual nurse.

In emergency cases, industrial nurses have a duty to determine the need for prompt medical attention, to make a tentative diagnosis of the patient's condition, and to employ necessary resuscitative and first-aid measures.

A PRUDENT WAY OF LIFE.—Perhaps Sir Thomas Lewis' description of a prudent way of life would not appeal to some of us, but its practice would no doubt be a forward step in the control of our nation's number one public health problem. "Very prudent people," said Lewis, "live quietly and moderately; they have their simple daily routine of work and pastime, enlivened by occasional excursions and entertainments, social gatherings and visits to and from their friends. They are temperate in their eating, taking no more than will maintain them in robust health, arranging their diet to consist chiefly of plain good food, relieved occasionally of its monotony by a more elaborate, but not heavy meal. They are regular in their habits of work and exercise, and in their mealtimes. They are strictly temperate in their drinking. They control their emotions and their passions. They avoid all forms of excess. They use tobacco little if at all. They welcome the freshness of abundant air and open spaces, delighting in the feelings of invigoration that accompany active exercise; they love the warmth of sunlight playing on their skins and the sleepiness of healthy fatigue. These are habits that few people in industrial countries now adopt, that fewer still maintain. The cares and distractions of an increasingly complex life, indoor or sedentary occupations, advancing years and the decreasing energy interfere less or more, and the prudent rules are neglected; neglect is the easier because the penalties, owing to the body's great power of resistance to disease, are uncertain in their incidence and often long deferred." Healthy habits would become more prevalent if the consequences of their neglect were more immediate and variable. Indeed, healthy habits, an optimistic philosophy, and the sound use of the abundant leisure which has made us the envy of the world, might well neutralize or retard the atherogenic mechanisms which are both initiated and accelerated by the "stress and strain" of our daily struggle for existence.—H. I. Russek, M.D., Emotional Stress and the Etiology of Coronary Artery Disease, editorial, *The American Journal of Cardiology*, August, 1958.

AMMONIA TOXICITY AND HEPATIC COMA

HEPATIC COMA, characterized by a flapping tremor, disturbed consciousness, and electroencephalographic changes, may occur in patients with cirrhosis of the liver or with portacaval shunts.[1] It is generally believed that under such circumstances toxic substances absorbed from the intestine may escape the normal detoxification processes in the liver and hence enter the systemic circulation and reach the brain. The identity of the toxic agent (or agents) in hepatic coma has not been fully established, but considerable evidence has accrued to implicate ammonia in this respect. Ammonia is normally present in appreciable amounts in the portal vein, due to intestinal absorption of ammonia derived from the bacterial breakdown of nitrogenous foodstuffs. Ordinarily this ammonia, together with the endogenous ammonia arising from the deamination of amino acids, is converted to urea by the liver, but in the presence of liver disease, or if the liver is bypassed, appreciable amounts may enter the systemic circulation. Blood ammonia levels are usually elevated in hepatic coma and coma may be precipitated in susceptible persons by the administration of ammonium salts or urea or by other factors capable of elevating the blood ammonia level such as a high-protein diet or gastrointestinal hemorrhage.[2] Additionally, avoidance of nitrogenous foodstuffs,[3] alterations in intestinal flora by chemotherapeutic agents,[4] or the removal of blood ammonia by dialysis [5] may result in clinical improvement.

Despite the apparent association between ammonia toxicity and hepatic coma, it has repeatedly been observed that blood levels of ammonia do not always reflect the severity of the symptoms of hepatic coma or the development of electroencephalographic changes.[6] A possible explanation of such discrepancies has recently been advanced by Warren and his associates.[7] These investigators postulated that, since ammonia is a weak base and since weak acids and bases are known to penetrate the blood-brain barrier largely in un-ionized form, the cerebral toxicity of ammonia should be influenced by the pH of the blood. In substantiation of this, they injected a number of ammonium salts (chloride, acetate, bicarbonate, and carbonate) into mice and found that the toxicity of the salts increased in direct relation to their ability to increase the blood pH. Further, when the LD_{50} of the various ammonium salts was injected into the animals, the brain ammonia concentrations proved to be essentially the same for each salt although the blood concentration of ammonia varied directly with the dosage, thus indicating that the lethal effect of ammonia is cerebral in origin. It was concluded that as the blood pH was increased by the injected salt the amount of un-ionized ammonia (NH_3) was increased relative to that of the ionized (NH_4^+) form. Since the normal blood pH is quite close to the pK of ammonia, small shifts in blood pH could be expected to significantly affect this ratio of un-ionized to ionized ammonia and hence profoundly influence the degree of penetration of the blood-brain barrier by the ammonia. Indeed the data reported indicate that changes of pH in the order of 0.1 unit result in a 50% rise in the concentration of ammonia in the brain. Such a phenomenon would explain the recently reported association of coma and alkalosis in patients with elevated blood ammonia levels [8] and the increased tolerance to infused ammonium observed in dogs receiving 10% carbon dioxide.[9] It also suggests that acidifying agents may be valuable adjuncts in the treatment of hepatic coma and indicates the futility of attempting to correlate the degree of cerebral intoxication by ammonia by determination of blood ammonia levels without taking into account the blood pH.

ORGANIZATION SECTION

REPORT OF THE COMMITTEE TO STUDY A. M. A. OBJECTIVES AND BASIC PROGRAMS

TO THE HOUSE OF DELEGATES AT THE CLINICAL SESSION, DEC. 2-5, 1958, MINNEAPOLIS

In our progress report to the House last June in San Francisco, we stated that our Committee was appointed by the Speaker pursuant to an action of the House in Philadelphia (December, 1957) modifying the recommendations of the Hyland Committee which earlier had been assigned the task of analyzing the report of the management consulting firm, Heller and Associates. Members of the House will recall that our Committee was requested to study four subjects: (*a*) redefinition of the central concept of A. M. A. objectives and basic programs; (*b*) placing more emphasis on scientific activities; (*c*) taking the lead in creating more cohesion among national medical societies; and (*d*) studying socioeconomic problems. This report sets forth our Committee's recommendations on these four topics.

At the conclusion of our report you will find the questionnaire and the two-page statement, "Genesis of the Committee," attached for your information. Inasmuch as all members of the House received the questionnaire, its inclusion here is merely for reference. Following the questionnaire itself are two long appendixes prepared for us by the Bureau of Medical Economic Research. Appendix A sets forth more than 1,600 quotations selected from the returned questionnaires. These actual words may mean as much to some members of the House as the statistical analysis of the returned questionnaires, which is the subject of Appendix B. In the latter, we would especially call your attention to the tests of the representativeness of the respondents to the questionnaire sent to a probability sample of physicians, members and nonmembers. These tests indicate that the respondents were so representative that replies from one or two thousand more respondents would probably have given the Committee very little additional information.

During our second meeting in San Francisco last June, the Committee reviewed progress on the survey, decided not to undertake a series of depth interviews, and made plans to terminate its investigation in order that the final report could be presented at the Minneapolis meeting. Our first meeting was held on March 15 of this year. The third meeting of the Committee was held in Chicago on Sept. 5 and 6 at which time this report was completed.

Your Committee's report is based on many informal conversations by members of the Committee, personal correspondence, the 1,600 selected quotations (Appendix A), the statistical analysis (Appendix B), and some 90 letters attached to the returned questionnaires. We are not reporting the results of a scientific opinion poll. The Committee wishes to make it clear that this report represents the views of the six members of the Committee aided by the materials furnished to it. At this time, we wish to thank the many members of the Association and a considerable number of nonmembers for their assistance.

The Setting

The Committee wishes to point out that any consideration of the four matters referred to it is circumscribed by the times in which we live. Medicine itself is changing rapidly; so rapidly that it seems to be exploding in many directions. The pace of advance in the science and art of medicine constantly amazes all of us. A year seldom passes without a new medical organization or health agency being born. Performance over a period of years may be necessary to determine whether these new organizations or agencies are genuinely medical or largely devoted to fund raising. This rapid pace of change has many other manifestations in our field of endeavor. Indeed, historians may record that the greatest accomplishment of the 20th century was that men learned how to die old instead of young. Apparently this greatest period of rapid mortality decline has run its course as the expectation of life at birth is now creeping upward very slowly from 69 years to 70 years. A continuation of the earlier rapid rise in this important statistical measure of life awaits further important developments in the medical management of the diseases of older life.

You have directed us to reexamine four important aspects of our Association. Every professional organization needs an occasional reevaluation. Your request comes at a time when the success of medicine in terms of length of life has reached a high and, at present, a rather stable level. For these great gains in the length of life the American people are grateful to us and to our fellow scientists. In our analysis of our Association, we have steadfastly kept in mind that the unique function of our profession which has distinguished it from other professions is that we have life on our hands. We are also mindful that in recent years medicine may

---

The historical background and appendixes to the report are available for study on a loan basis and may be secured by writing to the American Medical Association, Economic Research Department, 535 N. Dearborn St., Chicago 10.

have suffered more from its successes than from its failures. Progress in postponing death has come so rapidly in the past several decades that we must now recognize that the rate of progress can scarcely be continued at its frenzied pace. We make these brief observations in this preamble because these and other great factors are a part of the pattern provided us by our times; the problems of the American Medical Association are very much a part of the entire American scene. There are, of course, many socioeconomic factors involved even as there are in other fields about us. Among these are technology, industrialization, urbanization, unionization, inflation, and the rising percentage of older voters.

Asking for Criticism

When any long-established organization attempts rigorous self-criticism, some of its members and many outsiders may lift their eyebrows and question that it can be done. However, we submit that our attempts to obtain criticism have been highly successful. We have read and heard both favorable and unfavorable criticisms of every major activity of the Association and of every Headquarters' department; some were stated in rather vigorous language. The Committee is not confronted with an undersupply of criticisms. Moreover, the Committee is now convinced that a survey of the type such as we have conducted should be repeated every three or five years. In general, we would like to reassure the House that the volume of information we have received is quite sufficient for our purposes. Our problem is to utilize this wealth of material most effectively.

A few general comments on these preliminary observations seem warranted. Your Committee has been impressed with the great variety of ideas expressed. Interesting side lights have also been noted. For example, some of the extreme criticisms we received remind us of the young socialist who liked to banter his opposition with "I have a plan for increasing government control in the field of medicine. You don't have a plan for more government control. Therefore, I am doing positive thinking and your approach is negative and reactionary." Another side light was the unusual suggestion of a few respondents that the A. M. A. should immediately develop and insist on a minimum wage for interns and for residents. It will repay one to read all the 1,600 selected quotations in Appendix A. You will note many other side lights.

If it can be said that these many and varied criticisms point in any central direction, it would be that the central problem of our Association in the year 1958 is "splintering"—the dynamics of medicine are driving us in so many directions simultaneously. The result is more and ever more divisions and subdivisions in the practice of medicine. One may justly ask, is medicine organized or disorganized? The central imperative for our Association is to re-establish its leadership, and unify the fragments into a cohesive entity under one umbrella.

The Questionnaire Survey

Copies of this report, together with the appendixes, were mailed to the members of the House several weeks in advance of this meeting. We may now turn to a review of the questionnaire survey on each of the four topics assigned to us by the House. These topics were captioned A, B, C, and D in the questionnaire. Additionally, we include our findings and recommendations. At this point in our report we shall consider only the highlights of the statistical analysis of Appendix B.

During May our questionnaire was mailed to all members of the House and alternate delegates. It was also sent to the officers and trustees, 13 past-presidents, the editors of state and county society journals, the secretaries or executive secretaries of state and county medical societies, the secretaries of the American Boards, the national organizations of medical interest (listed periodically in THE JOURNAL), the deans of medical schools, and members of A. M. A. councils and committees. We shall refer to these as the black questionnaires because they were printed in black ink. Of this total of 2,938 mailed, 521, or 18%, were returned by the cutoff date for key punching and tabulation, July 11. (Actually 522, not 521, black questionnaires were used in the statistical analysis; see the first table in Appendix B for the number of usable returns and requested questionnaires.) The county medical societies accounted for 1,904 of the 2,938 black questionnaires mailed; 245 replies or 13% were returned; excluding the questionnaires sent to the county societies, the return was 27%. The members of the Committee were puzzled by the 34% return from the members of the House. However, we do recognize the pressures of time and circumstance, and are confident that the response obtained reflects a dependable consensus of that body.

The same questionnaire was printed in blue ink and mailed to 3,924 members and nonmembers, a probability sample, consisting of every 60th name in the punch card file. Only 497, or 13%, were returned; and 32 were unusable. Frankly, the Committee had expected a higher percentage of returns, considering the amount of publicity given to the project. The two most important explanations are that this type of request for criticism of the Association is new and the four topics assigned to the Committee and incorporated in the questionnaire are inherently difficult. The Committee was greatly pleased, however, by the wide scope of the replies as indicated by the selected quotations of Appendix A. Moreover, as set forth in detail in Appendix B, the 465 respondents to the blue questionnaire were a good cross section of the entire probability sample of 3,924 members and nonmembers as to age and state of residence. (The black questionnaires were sent to a stratified sample of persons holding certain positions.) Although the Committee was not trying to take a poll, the representativeness of the relatively small number of respondents to the blue questionnaire strongly suggests that a larger response would have added little to the Committee's knowledge. Over and above these technical considerations, your Committee recognizes that its task was to weigh and interpret the specific criticisms received and present to this House a series of observations and recommendations on each of the four topics assigned to it. Although our report will review the results as if there were four separate compartments corresponding to the four separate assignments given the Committee by the House, certain types of comments appear and reappear among the responses to all questions; for example, comments of a socioeconomic nature appear in the responses to every question although the Committee designed Part D for that purpose.

Part A

(Redefinition of the central concept of A. M. A. objectives and basic programs.)

The Committee instructed the staff of the Bureau of Medical Economic Research to break up each question, particularly those requesting comments, into a series of subquestions or categories to be phrased by the Bureau staff after an examination of several hundred replies. In editing the replies to Part A, it was found that 13 subquestions or categories could be used in coding and editing the replies to all three questions (see list of subquestions in Appendix A):

1. What is your idea of what the A. M. A. does for you? For the American public?
2. What do you think the objectives, aims, and goals of the A. M. A. should be?
3. Do you have suggestions for improving the service and effectiveness of the A. M. A.? Yes ☐ No ☐ If yes, please give them.

For example, many of the suggestions for improving the service and the effectiveness of the Association under question 3 were very similar to what other respondents suggested as the objectives, aims, and goals in question 2. Likewise, some of the respondents gave objectives, aims, and goals requested under question 2 in their replies to question 1 about what the A. M. A. does for you and for the American public. This same intermingling of questions 1, 2, and 3 was also noted in the 90 letters attached to the returned questionnaires. Thus, the responses to the three questions of Part A were considered under 13 subquestions or categories thereby displacing the original three questions. The essential unity of Part A has been preserved, but the separate quality of the three questions thereunder is somewhat blurred by this procedure. The five categories or subquestions mentioned most frequently by the respondents were numbered 2, 4, 5, 6, and 9.

2. *Scientific Information:* Improving, advancing. Dissemination to physician. Physician's informal post-grad. Publications, J. A. M. A., advertising. Scientific assemblies, exhibits. Research.

4. *Practice of Medicine:* Standards; maintaining or improving. Protection of M.D. Prestige. Osteopaths, relations with.

5. *Organization of Profession:* Leadership, official representation, coordination. Spokesman for profession, spokesman for physicians. Parent organization. Integration of groups within A. M. A. (e. g. Specialty and G. P.). Inter-group relationships within profession. Medical policies; positive vs. negative stand. Communication, county and state societies, and national level.

6. *Socioeconomic and Political Areas:* Study and dissemination of information. Representative spokesman for profession. Lobby. Physician's union. Socioeconomic and political policy. Cooperation with other professions and self-employed groups. Free choice of physician. Socioeconomic problems. Distribution of physicians. Cost of medical care. Insurance.

9. *Medical Care for Public:* Advancing, improving, individual and public health. Protection against quacks, improper drugs. Investigations.

The typical respondent to each of these questions mentioned two of these 13 categories or subquestions. In giving the replies to the three questions, 987 respondents "checked" a total of 5,726 of these 13 categories or subquestions. A total of 1,113 mentioned some objective or activity of a socioeconomic nature (number 6); 851 mentioned some phase of the organization of the profession (number 5). The differences in the rank order of the tabulations for the black and the blue questionnaires were not very marked. Among the black questionnaires the third most frequent response dealt with medical care for public (number 9), but practice of medicine (number 4) ranked third among the blue questionnaires. The subquestion or category ranked fourth among the black questionnaires was scientific information (number 2); among the blue questionnaires, medical care for public (number 9). Although the tabulations of these three questions set forth in Appendix B are worth study for the details provided, we conclude at this point that insofar as the responses received in our questionnaire survey are concerned, the socioeconomic function of our Association looms largest in the minds of our members. The 90 thoughtful letters and the reflections of the Committee further substantiate this conclusion.

As a result of these observations, your Committee concludes that the membership of the A. M. A. is convinced that the sociological and economic trends and conditions of today constitute an important aspect in the medical care of the patient and of the practice of medicine. Along with medical education, diagnostic medicine, therapeutic medicine, preventive medicine, Public Health medicine, and medical research—the art and science of medicine—sociological and economic aspects are integral parts of the unlimited health care of the people.

We, therefore, recommend that this House of Delegates consider the advisability of amending Article II of the Constitution by this substitution:

"The objectives of the Association are to promote the science and art of medicine and the betterment of public health, and an understanding of the socioeconomic conditions which will facilitate the attainment of these objectives."

Additional suggestions in the socioeconomic area are presented later in this report.

Part B

(Placing more emphasis on scientific activities.)

The second area, Part B, which the Committee was asked to investigate was scientific activities. Our broad interpretation of this was that we were to advise the House as to whether the scientific activities of the Association were generally adequate, generally inadequate, or about right. This was a large order for the questionnaire which we wanted to limit to 10 questions. (As has been pointed out already, some of our best information on one of the four parts of the questionnaire was actually included in the reply to another part.) The three questions follow:

4. Does the present degree of emphasis placed upon scientific activities by the American Medical Association meet with your approval? Yes ☐ No ☐ (Comments regarding specific activities will be appreciated by the Committee.)

5. Have you attended a midwinter Clinical Session? Yes ☐ No ☐ Do you consider these sessions valuable?

6. The Committee solicits your comments, if you have any, on the work of the A. M. A. bureaus, committees, councils, departments, divisions, and other agencies listed below. Please attach a reply if the lines provided below are not sufficient.

1. Bureau of Health Education
2. Bureau of Medical Economic Research
3. Committee on Legislation
4. Council on Constitution and Bylaws
5. Council on Industrial Health
6. Council on Medical Education and Hospitals
7. Council on Medical Service
8. Council on Mental Health
9. Council on National Defense
10. Council on Rural Health
11. Council on Scientific Assembly
12. Department of Public Relations
13. Division of Councils of Therapy and Research
    14. Council on Drugs
    15. Council on Foods and Nutrition
    16. Council on Medical Physics
    17. Bureau of Investigation
    18. Chemical Laboratory
19. General Manager's Office
20. Law Department
21. Judicial Council
22. Records and Circulation Department
23. Scientific Publications & Library
24. Today's Health
25. Washington Office

Of the returned black questionnaires, 86% indicated that the present degree of emphasis on scientific activities met with the approval of the respondents; the percentage on the blue questionnaires was 76. This overwhelmingly affirmative reply from those who chose to respond does conceal some of the important observations which the members of the Committee have read in the selected quotations in Appendix A. A few respondents claimed that many papers in The Journal were apparently chosen on the basis of when and where delivered rather than content and that the journals and the meetings of the specialty organizations were more valuable from the scientific standpoint.

In the matter of the Clinical Session, the number responding to the black questionnaire who had attended and who had not attended a clinical session was about equal, whereas the respondents to the blue who had not attended were about two and one-half times as numerous as those who reported they had attended. On the question of whether the midwinter Clinical Session is valuable, the ratio of "yes" to "no" on the black questionnaire was 5 to 1; and 4 to 1 on the blue questionnaire. In both groups, however, one-third to one-half did not reply.

The major purpose of question 6 was to set forth the 25 bureaus, committees, councils, divisions, and departments. Unfortunately, this question was left blank on more than half of the black and the blue questionnaires; fewer than one-third made specific comments on one or more of the 25 listed agencies of the Association. (See selected quotations in Appendix A.) A number of respondents wrote that this list of 25 agencies was an education to them; indeed, this was the primary purpose of the Committee in listing them. It was also felt that this list of 25 agencies might help respondents in answering other questions. Typically, respondents on the black questionnaire who gave a specific reply referred to three of these agencies and those on the blue questionnaire to two. It was very difficult to edit and code the responses to this question which might be said to have 25 parts. The first attempt was to classify the responses as favorable or unfavorable for the agency concerned. For example, consider a respondent who after indicating disagreement with a specific A. M. A. policy severely criticized the agency which published items in support of that policy. Should this reply be considered favorable or unfavorable criticism of the specified agency? Since no agreement could be reached on a consistent pattern of interpretation of comments as being favorable or unfavorable and the replies were so few, the Bureau of Medical Economic Research was asked merely to tabulate the number of mentions of each of the 25 agencies. Despite the small number of replies, it may be helpful to note that the Council on Medical Education and Hospitals, the Department of Public Relations, the Washington Office, and the Council on Drugs were mentioned (favorably or unfavorably) most frequently.

The conclusion of Part B on the subject of whether our Association should or should not place more emphasis on scientific activities is that there are no widespread dissatisfactions with the Association's present emphasis on scientific activities as a whole, so far as is revealed by a mere count of the replies of the respondents. But the selected quotations (see Appendix A) and our own observations indicate some measure of dissatisfaction. Scientific progress is never-ending. Your Committee strongly advises the Board of Trustees to give serious consideration to the establishment of some more effective mechanism to insure continued study of the scientific activities of the Association with the ultimate intent and purpose of revamping and otherwise changing them as deemed necessary. Your Committee understands that there is already a "special committee to study scientific activities," but it is believed that the scope of the "special committee" is too limited. This thought about the scope of a study of scientific activities of the Association will be more fully developed in a section of this report to follow.

Part C

(Taking the lead in creating more cohesion among national medical societies.)

The third part of the Committee's assignment was to examine the need for creating more cohesion among national medical societies. Questions 7 and 8 of Part C were designed to provide the Committee with specific advice on this problem of the relationship of our Association to other national medical organizations with an invitation for comments on question 7, but not on question 8.

7. Do you approve of the present relationship between the American Medical Association and other national medical organizations? Yes ☐ No ☐ (The Committee would welcome your suggestions for changes in the relationship of the A. M. A. to a named national medical organization[s].)
8. Do you believe that independent action among national medical societies promotes or impedes progress toward the goals of the medical profession? Promotes ☐ Impedes ☐
If you believe that more cohesion among national medical societies is desirable, please indicate in which of the three areas: Scientific ☐ Socioeconomic ☐ Both ☐

Among the respondents to the black questionnaire a ratio of better than 3 to 1 approved the present relationships; check marks on the blue questionnaire agreed with the ratio of more than 3 to 1. This was a very general appraisal of our relationships with the other national organizations. Although the comments offered in addition to the check marks were fewer than we had hoped, it is apparent that some respondents doubt that the A. M. A. is still the recognized leader of the profession. This type of comment was also given in Parts A and B. Others believe that more coordination is desirable particularly in regard to the meetings of the other national organizations—a comment which might have been given to question 8 if the Committee had provided lines for comments. There was a wide scatter of other comments, but the relationships with the American College of Surgeons and the American Academy of General Practice were featured. The phrases excerpted from the comments on question 7 provided the Committee with some illuminating details.

The Committee sought to obtain additional light on this problem of relationships by asking only for check marks in question 8. The replies on the black questionnaire produced a tie on the question of whether independent action among national medical societies promotes or impedes progress toward the goals of the medical profession. Recognizing that we are reporting to you information derived from a small sample, we believe that this even division between the pros and cons is worth noting. Among the respondents to the blue questionnaire, the ratio was about 3 to 2, three "promotes" and two "impedes." In our desire to offer you a few objective questions requiring only check marks for your answers we did not invite comments regarding what "promotes" and what "impedes" progress toward our goals in the first part of question 8. The Committee was aided, however, by comments on the question of relationships with other national medical societies which were recorded among the responses to other questions.

From the replies to this second part of question 8 it is clear that the respondents believe that more cohesion is needed in both scientific and socioeconomic areas, with somewhat more stress on the latter. Moreover, the respondents to the black and the blue questionnaires were generally in agreement, although the latter placed slightly more stress on the scientific areas than did the former. In other words, the respondents, whether they thought independent action promotes or impedes progress toward the goals of the medical profession, told us that more cohesion among national medical societies is desirable. In the light of what the Committee learned from the responses to Part C, from the phrases excerpted from the replies to the other parts of the questionnaire, and on the basis of our own observations and discussions with a wide variety of physicians, we recommend that a more thorough study should be made of our relationships with other national medical organizations with a view to improving them and to reasserting A. M. A. leadership in socioeconomic areas particularly and to the maximum extent in scientific areas.

In order to accomplish these objectives, we recommend that the Board of Trustees in establishing a mechanism for the continued study of the scientific activities of the A. M. A. insure that that mechanism will assume the responsibility for establishing active liaison with each national medical society. The intent of this liaison should be to explore all fields of interrelationship between the A. M. A. and the national medical societies. There should be an attempt to define the area of activity of each organization. In the scientific fields the role of the A. M. A. might be primarily that of coordination between the special fields of scientific interest of the other national medical organizations. Improved cohesion between these organizations and the A. M. A. could result if the A. M. A. were to abolish its scientific sections and invite these national organizations to furnish the specialty and General Practice programs at each annual session. This possibility at least deserves study, and if it were to prove practicable, the participating other national medical organizations might be given the representation in the House of Delegates vacated by the scientific sections as they are abolished.

In view of the many comments in Appendix A concerning the voluntary health agencies, it is equally important to insure that the mechanism for continued study of scientific activities of the Association include provision for the establishment of close liaison with those health agencies for the mutual benefit of the agency, the profession, and the public.

Part D

(Studying socioeconomic problems.)

The fourth part of our assignment was to study socioeconomic problems. As already noted, comments of a socioeconomic nature were prominent in the responses to Parts A, B, and C of the questionnaire. So great was the ground swell of comments of this character that we could not compartmentalize them in Part D. Question 9 was our second objective type question requiring a Yes or No answer, on a choice of three socioeconomic policies.

9. How far should the A. M. A. go in the socioeconomic field? Please check one of the following three: a. Should the A. M. A. limit itself to matters of prime concern to the health of the people of the nation? Yes ☐ No ☐. b. Or should the A. M. A. interest itself in socioeconomic factors of America which affect the health of the people of our nation and the practice of medicine? Yes ☐ No ☐. c. Or should the A. M. A. also interest itself in socioeconomic issues whether or not they directly affect the health of the people of our nation or the practice of medicine? Yes ☐ No ☐

10. What socioeconomic policies of the A. M. A. do you approve or disapprove?..

A number of respondents answered more than one of the three, but the overwhelming proportion of check marks on policy "b" provided us with a definitive answer.

Socioeconomic policy "a" was not popular. In the black questionnaires the single responses were 35 to "a," 281 to "b," and 93 to "c"; considering respondents who checked more than one answer, those stressing policy "a" numbered 57, "b" numbered 364, and "c" numbered 154. The responses on the blue questionnaires present substantially the same result with great emphasis on policy "b."

Your Committee concludes, therefore, that the A. M. A. should not "limit itself to matters of prime concern to the health of the people of the nation." It should "interest itself in socioeconomic factors which affect the health of the people of our nation and the practice of medicine." Supported by the results of the returned questionnaires and other sources, we would conclude that the A. M. A. should not interest itself in "socioeconomic issues whether or not they directly affect the health of the people of our nation or the practice of medicine." We submit that a comprehensive history of the American Medical Association would indicate that policy "a" was favored in an earlier era. Indeed, we believe that policy "c," the almost unbounded scope of socioeconomic interest, may well be the policy toward which our Association is now moving. Obviously, a constantly increasing number of our members realize that good health is dependent not only upon good medical care but also upon good food, good clothing, good housing and good sanitation as well, and that their dual responsibility as physician and citizen makes imperative an active participation by their Association in any and all legitimate activities directed toward that goal. We commend these findings to this and future sessions of the House of Delegates without specific recommendations for changes in the Constitution or the establishment of a 10-point or 20-point socioeconomic program.

The tremendous emphasis in this questionnaire survey on socioeconomic policies was one of the surprises to our Committee. It seems that no matter which questions we asked about objectives and policies, and/or how we worded them, the socioeconomic aspects were somehow emphasized by respondents. (See Appendix B.) No longer can it be claimed that our Association is not interested and should not be interested in socioeconomic factors of American life.

In framing question 10 the Committee thought it wise not to specify socioeconomic policies by name. Responses indicating general approval, though few in number, greatly exceeded responses indicating general disapproval of Association policies. Almost half of the respondents commented on one or more specific policies. In coding and editing the responses, 19 policies were mentioned often enough to warrant tabulation. As stated in the preamble, we consider it of critical importance that the House positively know this to be a committee's report and not a statistical report of the results of a scientific poll of opinion. Hence, it would serve no purpose to report on the tabulations separately for and against a specific policy. Approval or disapproval of the Association's stand on socialized medicine was mentioned most frequently, with approval or disapproval of the Association's position on social security coverage for self-employed physicians ranking second, followed by approval or disapproval of Association policy on the extension of voluntary health insurance. The fourth most popular item was approval or disapproval of what we were forced to call "publicizing policies." As noted, many of the responses to other questions have provided useful information to the Committee on socioeconomic policies. Curiously, the Forand bill and the third party problem ranked below all four of these policies.

Part E

(Classification of Respondent.)

The last section of this questionnaire survey, Part E, provided for the classification of the respondent. As shown in Appendix B, the distributions by age and by state of those who responded to the blue questionnaire and those who did not respond were quite similar. Although the IBM punch card file could not be used for testing the representativeness of the respondents as to type of practice, form of active private practice, and size of city, the fact that the distributions by age and by state were reasonably similar suggests that the respondents were representative of the entire group of 3,924 in the probability sample to whom blue questionnaires were mailed. This fact fortifies the Committee's confidence in the questionnaire survey results. Since the black questionnaires were sent to a stratified sample in which the number of county medical society secretaries loomed so large, a similar test of the representativeness of the respondents to the black questionnaires was not even attempted.

Most of the respondents on the black questionnaire reported that they are A. M. A. members, as did more than four-fifths of those who responded to the blue questionnaire in the probability sample. We are pleased to report that 9 out of 10 respondents to the black questionnaire signed it; and 8 out of 10 who responded to the blue questionnaire did likewise.

General Conclusions

In the foregoing we have set forth our findings, suggestions, and some recommendations on each of the first three topics which you assigned to our Committee. We turn now to more general conclusions including our recommendations on the fourth topic.

First, the members of the Committee were in unanimous agreement that it should be discharged although the task is not finished. Indeed, our studies definitely indicate this to be a continuous task. A reasonably complete set of recommendations would require more study and consideration of the setting provided by the rapidly changing medical, economic, social, and political events of our times, such as a continuous study would eventually reveal. Periodic self-examination is highly desirable, especially at this juncture in the development of our Association, the practice of medicine, and the rapidly changing social scene in the United States.

Second, we recommend the establishment for a period of three years of a Council or Committee on Socioeconomics to investigate socioeconomic and related problems with which the Association is likely to be confronted in future years. This council or committee could be of five members who should be appointed by our President, the Speaker of our House, and the Chairman of our Board of Trustees. This council or committee should have power to hold conferences with any and all individuals or groups who might develop ideas of aid to our Association and its purposes. This council or committee should report to the Board of Trustees and to the House of Delegates. During its three-year tenure, this committee or council should find its place in our Association activities and the House and Board of Trustees should review its work thoroughly before its activities are continued beyond the three-year period. Your Committee hopes that the materials we have provided will chart a course for this new council or committee.

Third, your Committee recommends that the Board of Trustees give serious consideration to opening the publications of the Association to a free and open discussion of socioeconomic problems *applicable to medicine. Members and officers* of the Association should be encouraged to contribute items to this section of the publication, or publications; and a special invitation should be extended to the many able persons on our Headquarters' staff. In the words of a member of our Committee, "We must restore to our members the feeling of belonging." We must not stifle constructive criticism; forward-looking discussions of any and all future problems should be made available to our members.

The Committee is thoroughly convinced that the A. M. A. must vigorously reassert its leadership in American medicine. We must cease the splintering tactics so disastrous to French politics. We must not become a disorganized profession. A more vigorous and more deliberately developed socioeconomic program toward this end is imperative.

At this point, your Committee wishes to direct special attention to the time-consuming, painstaking, thoroughgoing, and most effective work performed by Dr. Frank G. Dickinson and his staff, Dr. Leonard W. Martin, research associate, Olga Stetsuk and Cynthia Harkness, research assistants, of the Bureau of Medical Economic Research.

From the outset of our activities, Dr. Dickinson gave us expert counsel and guidance in the preparation of the questionnaire and in the method of its distribution among our members and nonmembers. In innumerable other ways he brought to our activities the experience and perspective of the expert statistician which are invaluable to any survey; but particularly so in the sensitive area of socioeconomic policies applicable to the American Medical Association.

We would especially emphasize the manner in which Dr. Dickinson and his staff have analyzed the responses to the questionnaire, have broken them down into subquestions, and have catalogued these responses in a manner designed to make our task much easier and our report more meaningful. The selection of some 1,600 quotations from the returned questionnaires—an ingenious procedure—presented in Appendix A has made us feel that the respondents were invisible members of our Committee. The statistical analysis of the returned questionnaires (Appendix B) reflects the consensus of an important cross section of informed and interested physicians throughout the country.

Finally, we wish to thank again all members and nonmembers who have counseled with us, those who returned their questionnaires, and particularly those who wrote us the 90 letters of more than 180 pages.

REPORT OF REFERENCE COMMITTEE

Report of Committee to Study A. M. A. Objectives and Basic Programs.—Your reference committee has spent an unusual amount of time in studying the report of the Committee to Study A. M. A. Objectives and Basic Programs and in listening to the free discussion in the open session. Truly heartening is the tremendous interest manifested by the respondents to the questionnaires, by oral discussions in small groups, and by the spirited review before the reference committee. It may be that this report will be a most significant milepost in the history of the American Medical Association.

With the far-reaching changes that have evolved in the socioeconomic and political areas of this country, it is logical that an organization such as the A. M. A. can profitably take stock of its expressed objectives or purposes, and its basic programs of service and activity. The work of this Committee has proved that American physicians can evaluate themselves professionally, and as citizens; can recognize areas of needed improvement; and can outline practical ways of maintaining the highest standards of health in this country, within the framework of private enterprise, the truly American way of life.

In a sincere desire to stimulate progress in medicine in every specialty and area, the A. M. A. has encouraged specialty societies, and it is only natural that in the multiplicity of medical groups the stature and prestige of the parent organization may not be so apparent. But it is easily possible for the A. M. A. to continue as the "fountainhead" of virile, worthwhile scientific groups, and yet sponsor such a bold, vigorous, constructive, logical program that its leadership will be recognized and respected more than ever before.

Clearly the members of the A. M. A. are convinced that sociological and economic trends and conditions of today constitute an important aspect in the medical care of the patient and of the practice of medicine.

Your reference committee recommends that the first recommendation of this special committee—that the House of Delegates consider amendment of Article II of the Constitution by this substitution: "The objectives of the Association are to promote the science and art of medicine and the betterment of public health and an understanding of the socioeconomic conditions which will facilitate the attainment of these objectives"—be referred to the Council on Constitution and Bylaws.

Your reference committee recommends that the Board of Trustees establish a mechanism which will assume the responsibility for promoting active liaison with each national medical society. The intent of this liaison should be to explore all fields of interrelationship between the A. M. A. and the national medical societies. There should be an attempt to define the area of activity of each organization. In the scientific fields the role of the A. M. A. might be primarily that of leadership, but every endeavor should be made to bring about coordination of the special fields of scientific interest of the other national medical organizations.

Since the Board of Trustees in Supplementary Report L has announced a very comprehensive plan to establish and develop a Division of Socio-Economic Activities, your reference committee feels that there is no necessity for the creation of a new council or committee on socioeconomics. The House of Delegates will be informed periodically on the progress of this new Division of Socio-Economic Activities through the medium of semiannual reports to the House and the regular media of publications.

Your reference committee approves the recommendation that the Board of Trustees give serious consideration to opening the publications of the Association to a free and open discussion of socioeconomic problems applicable to medicine. Members and officers of the Association should be encouraged to contribute items to this section of the publication or publications.

The Committee to Study A. M. A. Objectives and Basic Programs has served faithfully and correctly points out that the assignment given to it by this House last December was so comprehensive that no one group could be expected to cover the responsibilities completely, particularly in the space of a few months.

Since it is apparent to your reference committee that the work of analysis and improvement of basic programs of the A. M. A. will continue through the mechanisms mentioned in this report, this special committee should be relieved of further responsibility and we so recommend, with the additional recommendation of an expression by this House of Delegates of deep appreciation and thanks for a task well done. Special thanks are also due Dr. Frank G. Dickinson and his staff of the Bureau of Medical Economic Research for the tremendous service rendered in preparing this report. We urge every delegate to study his copy of the report very carefully and urge every physician to review with interest the printed summary and other comments in THE JOURNAL.

MEDICAL NEWS

COLORADO

Dr. von Kaulla Participates in Broadcast.—Dr. Kurt N. von Kaulla, a member of the University of Colorado School of Medicine faculty, recently participated in a discussion which was recorded for broadcast throughout Europe by the Voice of America. He is one of four German-speaking researchers invited by the U. S. State Department to take part in the recorded discussion during a symposium on blood conducted at Wayne State University, Detroit. The 15-minute transcribed discussion concerned, among other subjects, progress made in America in dissolving blood clots. On the panel with Dr. von Kaulla were three research scientists visiting in the U. S., and representing Germany, Austria, and the Netherlands.

ILLINOIS

Meeting of Anesthesiologists.—The Illinois Society of Anesthesiologists will convene March 21 at the Lin [illegible] Beach Hotel, Chicago, with dinner at 7 p. m. and the scientific program beginning at 8 p. m. "The Limitations of Anesthesia in Poor Risk Patients" will be given by Dr. James E. Eckenhoff, professor of anesthesiology, University of Pennsylvania, Philadelphia. Reservations for dinner ($5.30) must be made not later than March 14. For information and reservation write Dr. Frank M. Grem, 546 N. Elmwood Ave., Oak Park, Ill.

Engineers Aid Medical Research.—Thirty-five Illinois Bell Telephone Company engineers have volunteered their know-how to help medical research in fighting cancer, heart disease, and infant deaths. New instruments resulting from their spare-time efforts were demonstrated Feb. 5 for the first time at the University of Chicago. The volunteers belong to an organization called SAVE—Service Activities of Volunteer Engineers. They have reported that accomplishments of the first year of work included:

1. Completion of working models of a three-ounce device to count the human heartbeat while being worn during a full day of normal activity.
2. Virtual completion of a training machine to teach laboratory technicians to identify cancer cells under the microscope.
3. Progress toward an electronic computer that instantaneously reports changes in the volume of air in the lungs of a baby in the hope of detecting hyaline membrane disease.
4. Progress toward an electronic circuit 10 times more sensitive than existing equipment to radiation from radioisotopes trapped in brain tumors.
5. Under development is an electronic calorimeter, which is a cumulative recording device to measure changes in body heat. Such an instrument would aid in studies of metabolism.

Another device is an electronic stethoscope. The idea for SAVE originated with William V. Kahler, president of Illinois Bell and a trustee of the University of Chicago. After consulting with physicians at the University of Chicago Clinics, the engineers set to work in basements, garages, and workshops at their homes in 20 suburbs and throughout Chicago. All the instruments developed through the efforts of SAVE reportedly will be put at the disposal of the medical profession. An enlarged report on SAVE will appear in the Medicine at Work section of THE JOURNAL, issue of March 21.

Chicago

Dr. Cooper Honored.—Dr. John A. D. Cooper, professor of biochemistry and assistant dean of Northwestern University Medical School, recently was honored by the University of Brazil when it conferred on him the degree of Doutor Honoris Causa, "in recognition of the work done in helping to establish and equip a radioisotope laboratory in the Institute of Biophysics at the university's medical school."

Annual Medical History Lecture.—The annual D. J. Davis Memorial Lecture on Medical History will be given at 1 p. m., Wednesday, April 22, in Room 221 of the Dental–Medical–Pharmacy Building of the University of Illinois, 1853 W. Polk St. The lecturer will be Dr. Lloyd G. Stevenson, professor of the history of medicine and dean of the Faculty of Medicine, McGill University, Montreal P. Q., Canada. His subject will be "The Early Development of Internal Medicine in the United States."

Lectures in Research in Cancer.—The last two lectures in the University of Chicago 1959 Winter Quarter series on Research in Cancer are arranged as follows: March 9, 5 p. m., "The Contribution of Experimental Gliomas to Human Disease," Dr. Harry M. Zimmerman, chief, Laboratory Division, Montefiore Hospital, New York City; March 16, 5 p. m., "Viral Etiology of Mouse Leukemia: Its Possible Implications for the Problem of Cancer," Dr. Ludwik Gross, chief, Cancer Research Unit, VA Hospital, Bronx, N. Y.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Hospital News.—Michael Reese Hospital and Medical Center has announced the appointment of Dr. Morris Weiss to the position of first Medical Director of Mandel Clinic, the Hospital's out-patient division. In this new position, Dr. Weiss, who was assistant professor of medicine, Baylor University College of Medicine, Waco, Texas, from 1956 to 1957, will be responsible for all medical care and education given at the clinic.

KANSAS

Centennial for State Society.—On Feb. 10 the charter issued by the Territorial Legislature of Kansas was 100 years of age and the Kansas Medical Society which was given "perpetual succession forever" survived its first century. The centennial is to be commemorated until the close of the annual session to be held in Topeka, May 4-6. A special program based on a frontier theme necessitates that the meeting be held at the Fairgrounds. Many events for public participation have been planned. A Hall of Health with educational exhibits for the public will be open for two weeks prior to the annual session. A book, "A Century of Medicine in Kansas," has been written with the cooperation of the Committee on History. The National Rural Health Conference at Wichita March 5-7, is also a part of the society's centennial celebration.

MAINE

Conference on Mental Retardation.—The first International Medical Conference on Mental Retardation, organized by the Maine Chapter of the American Academy of Pediatrics, the Division of Maternal and Child Health, Maine Department of Health and Welfare, and the Pineland Hospital and Training School, Pownal, will be held July 27-31 at the Eastland Hotel, Portland. The program will include in its five days of general sessions addresses on brain anatomy, the reticular system, head anomalies, phenylketonuria, lipoids, birth injury, embryology, infections, mongolism, erythroblastosis, therapy, psychiatry, psychology, and behavior disorders, by "outstanding authorities" on these subjects. Not intended to answer all questions on the problems concerning mental retardation but rather to construct the problems which have to be attacked scientifically, the conference is open to all physicians throughout the United States, Canada, and other countries, following immediately after the International Pediatric Congress at Montreal, Canada. For information write Dr. Ella Langer, State of Maine, Department of Health and Welfare, Augusta, Maine, Chairman, Arrangements Committee.

MARYLAND

Hygiene Lecture.—As part of the De Lamar Lectures in Hygiene of the School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, a public lecture on "The Long Range Effects of Ionizing Radiations on the Individual" was presented by Dr. William R. S. Doll, lecturer in medical statistics and epidemiology, London School of Hygiene and Tropical Medicine, England, Feb. 20.

MASSACHUSETTS

Medical History Meeting.—The next meeting of the Benjamin Waterhouse Medical History Society will be a combined meeting with the Providence Medical Historical Society to be held at the Massachusetts Memorial Hospital, Monday, March 16. Dr. Seebert J. Goldowsky, director, Peripheral Vascular Clinic, Rhode Island Hospital, will be the speaker, presenting, "The Hospital at Portsmouth Grove." For information and reservations write Dr. John J. Byrne, 818 Harrison Ave., Boston 18, Secretary (KE 6-8600).

Dr. Bandler Named Department Chairman.—Dr. Bernard Bandler, of Cambridge, president-elect of the American Psychoanalytic Association, has been named chairman of the department of psychiatry at the Boston University School of Medicine. He has also been named psychiatrist-in-chief of the Massachusetts Memorial Hospitals. He has been associated with the school and with the hospital since 1947. Dr. Bandler is currently chairman of the Ad Hoc Committee on Education in Public Hospitals of the American Psychiatric Association in liaison with the American Psychoanalytic Association, a member of the executive committee of the American Psychoanalytic Association, training analyst for the Boston Psychoanalytic Society and Institute, Inc., and a member of the Medical Advisory Committee of Boston University's Sargent College.

MICHIGAN

Sight Testing for Children.—The eyesight of 325,837 Michigan school children was screened in 1958 by technicians employed by local health departments and local schools, the Michigan Department of Health has reported. Each child was screened for nearsightedness, farsightedness, astigmatism, and muscle imbalance. Of the children screened, 37,035 (11.5%) were referred to doctors to have an eye examination for the first time. During 1958, 57 children were added to the state health department's Register of Children with Severe Visual Handicaps. Nine hundred and thirty-nine youngsters are now registered, 187 whom are of preschool age.

MISSOURI

Dr. Sante Receives Radiology Award.—Dr. LeRoy Sante, professor of radiology and director of the department, Saint Louis University School of

Medicine, received a gold medal award from the American College of Radiology at ceremonies in Chicago Feb. 6, during the college's annual convocation. Dr. Sante was one of three radiologists throughout the country unanimously chosen for the award by the board of chancellors of the college. The gold medal award is presented annually "for distinguished and extraordinary service to the American College of Radiology and to the profession for which it stands." The award also will be presented posthumously to Dr. C. Edgar Virden, formerly chief of the radiologic service at St. Joseph's Hospital, Kansas City, Mo., and to Dr. Robert S. Stone, director of the department of radiology, University of California.

MONTANA

Joint Meeting in Missoula.—The Montana Heart Association and the Montana Trudeau Society will sponsor a joint meeting in Missoula, April 17-18. All sessions will convene at the Florence Hotel and all physicians and interested lay people are invited. The speakers at this meeting will include Dr. Herbert E. Griswold, chairman, department of cardiology, University of Oregon Medical School, Portland; Dr. Richard E. Fowler, professor of pediatrics, Tulane University School of Medicine, New Orleans; Dr. Walter M. Kirkendall, clinical associate professor of internal medicine, State University of Iowa College of Medicine, Iowa City; Dr. David T. Smith, professor of bacteriology and associate professor of medicine, Duke University School of Medicine, Durham, N. C.; Dr. Jay A. Myers, professor of internal medicine, University of Minnesota Medical School, Minneapolis; and Dr. Carroll J. Martin, Seattle Sanitarium.

NEW JERSEY

Dr. Stevenson Named Department Chairman.—Dr. Stuart S. Stevenson was appointed professor and chairman of the department of pediatrics, Seton Hall College of Medicine, Jersey City. Dr. Stevenson, whose appointment was effective March 1, comes to Seton Hall from the University of Pittsburgh School of Medicine, where he has been acting chairman of the department of pediatrics. In addition, he was acting medical director and chief of staff at the Children's Hospital in Pittsburgh. He is chairman of the Committee on Residency Fellowships of the American Academy of Pediatrics.

NEW YORK

Dr. Weinberg to Lecture on Hypnosis.—The New York County Chapter of the American Academy of General Practice will present Dr. Abraham Weinberg, chairman, Committee on Mental Hygiene, New York Academy of General Practice, and lecturer in medical hypnosis, Seton Hall College of Medicine, March 12, 9 p. m., room 65 at the Academy of Medicine, 2 E. 103rd St., New York City. Dr. Weinberg will discuss "Indications and Techniques of Hypnosis for the General Practitioner." For information write Dr. Stanley H. Greenwald, 325 E. 79th St., New York 21, Secretary.

Personal.—The provisional appointment of Dr. Ray K. Brown as associate director of the State Health Department's Division of Laboratories and Research effective Jan. 29, has been announced by Dr. Herman E. Hilleboe, state health commissioner. Dr. Brown has served since 1953 as assistant director of the department's Laboratories for Biochemistry and Immunology.——Dr. James W. Bartlett Jr. has been named assistant dean of the University of Rochester School of Medicine and Dentistry. He is in charge of admissions and will assist in administration of scholarships and loans. Dr. Bartlett is an instructor in the department of psychiatry.

OHIO

Dr. Dods to Give Rachford Lectures.—The 27th annual series of the Benjamin Knox Rachford lectureships will take place in Cincinnati April 21 and 22, at 8:30 p. m. Dr. Lorimer F. Dods, professor of child health at the University of Sydney, Australia, will deliver these lectures in the auditorium of the Children's Hospital Clinic and Research Building. On April 21 Dr. Dods will lecture on "Pædiatrics in the Antipodes," and on April 22 his subject will be "Some Pædiatric Philosophy."

PENNSYLVANIA

Bicentennial Week in Pittsburgh.—The Pittsburgh Bicentennial Lecture Week in Medicine was held during the last week in February. Four lectures were presented in the University of Pittsburgh Schools of the Health Professions auditorium. Guest lecturers were Theodore T. Puck, Ph.D., chairman, department of biophysics, University of Colorado School of Medicine, Denver; Dr. George W. Thorn, Hersey professor of theory and practice of physic, Harvard Medical School, Boston; Dr. Carl V. Moore, chairman, department of medicine, Washington University School of Medicine, St. Louis; Dr. Charles W. Mayo, head, surgery section, Mayo Clinic, Rochester, Minn.

Philadelphia

Annual Lecture.—The Kappa Pi Chapter of the Phi Delta Epsilon Fraternity will hold its annual Bernard Comroe lectureship series March 20 in the Medical Alumni Hall of the Hospital of the University of Pennsylvania. The guest speaker will be Dr. Harold G. Wolff, professor of medicine (neurology), Cornell University Medical College, New York City. His subject will be "Headache."

Dr. Koprowski Receives French Award.—Dr. Hilary Koprowski, director of the Wistar Institute of Anatomy and Biology and president of The New York Academy of Sciences, received the cross of a commander of the Ordre du Merite pour la Recherche et l'Invention from the Societe d'Encouragement pour la Recherche et l'Invention (French) at a ceremony in the Wistar Institute museum Feb. 11. The Societe d'Encouragement pour la Recherche et l'Invention was formed in 1901 under the sponsorship of the French government ministries of education, public health, and industry and commerce. A committee composed of authorities in the various fields of science chooses a few researchers and inventors of high standing each year for awards of various degrees in the society's Ordre du Merite. Dr. Koprowski is chairman of the Inter-American Society of Microbiologists and a member of the virology and rickettsiology study section of the National Institutes of Health.

TEXAS

Steel Company Donates Community Hospital.—Hospital in the Pines, a 30-bed hospital costing more than 30 million dollars and built by the Lone Star Steel Company, was turned over to the people at a formal dedication ceremony recently. The president of the company, Mr. E. B. Germany, presented the title to the board of directors. The gift of the hospital was noncommittal, and the Steel Company will have no voice in the hospital management. The board of seven members will be entirely independent of the company. Mr. Thomas K. Ewan, chairman of the board, accepted the hospital in behalf of the board at the ceremony. In the spring of 1956 Lone Star Steel employed an independent firm of hospital consultants to determine the site that would best serve the area. Local civic and business leaders organized Hospital in the Pines, Inc. and the charter was granted in 1957. The design will permit later expansion. Dr. Lowell E. Rutledge, of Daingerfield, is chief of staff.

GENERAL

Fellowships in Forensic Pathology.—Under the auspices of the College of American Pathologists, there is a vacancy for a fellow in forensic pathology for a period of six months' training at the Armed Forces Institute of Pathology. Stipend is $2,500. Six months' credit toward the Subspecialty Certificate in Forensic Pathology given by the American Board of Pathology will be allowed to the individual filling this fellowship. Interested individuals may apply to the AFIP or to Dr. Russell S. Fisher, Chairman, Committee on Forensic Pathology, College of American Pathologists, Prudential Plaza, Chicago.

Fraternity Meeting in Miami Beach.—The seventh annual interim scientific meeting of Phi Lambda Kappa, national medical fraternity, will be held at the Deauville Hotel, Miami Beach, Fla., April 5-12. The five-day program, starting Monday, April 6, will be for the benefit of the general practitioner and will feature papers and symposiums by specialists in their fields. All members of the medical and dental professions are welcome. For registration and information, write Dr. Samuel L. Lemel, 1621 Euclid Ave., Cleveland 14.

Tri-State Association Meets in Winston-Salem.—The annual meeting of the Tri-State Medical Association for Virginia, North Carolina, and South Carolina will be held March 16-17 in Winston-Salem, N. C. Five panel discussions are arranged: "Gastroenterology," "Dermatology," "Psychiatry," "Cardiac," and "Trauma." The following papers will be presented:

Urology—A New Surgical Approach for the Correction of Urinary Incontinence, Dr. L. T. Pennington, Greensboro, N. C.
Infertility, Dr. John Monroe, Winston-Salem, N. C.
Hypnosis in Pregnancy, Dr. T. W. Littlejohn, Durham, N. C.
Radiation Hazards, Dr. I. Meschan, Winston-Salem, N. C.

Guest speaker at the banquet at 7 p. m., March 16, will be Dr. Robert F. Clodfelter, of Winston-Salem.

Meeting on Anesthesia Research in Miami Beach.—The 33rd congress of the International Anesthesia Research Society will be held April 20-23 in Miami Beach, Fla. Papers to be presented by foreign participants include the following:

Anesthesia for the Ambulant Surgical Patient, Dr. Eric Webb, Vancouver, British Columbia, Canada.
A Method of Anaesthesia for Per-Oral Endoscopy, Dr. J. D. A. Firth, Montreal, Quebec, Canada.
Anesthetic Techniques for Tonsillectomy and Adenoidectomy in Children, Dr. Oscar V. Ribeiro, Rio de Janeiro, Brazil.

Three panel discussions are planned: "Open Cardiac Surgery," "Recurrent Staphylococcal Infections in Modern Hospitals," and "Pharmacology." Two movies are scheduled, and discussions will conclude each session.

Aero Medical Meeting in Los Angeles.—The 30th annual meeting of the Aero Medical Association will be held April 27-29 at the Statler Hilton Hotel, Los Angeles. Brig. Gen. M. S. White, M. C., USAF, president of the association, will open the program with an address, followed by the Louis H. Bauer Lecture, presented by Dr. Hans Selye, Faculty of Medicine, University of Montreal, on "Stress in Aviation Medicine." Two symposiums are planned: "Aeromedical Aspects of Stress," with Dr. Selye as chairman, and "Toxicological Health Hazards," with Col. Harold V. Ellingson, M. C., USAF, director of education and plans, USAF School of Aviation Medicine, Randolph Air Force Base, Texas, as chairman. The program will include speakers from Canada, England, Italy, France, Germany, and Norway. For information write Dr. T. H. Sutherland, P. O. Box 26, Marion, Ohio, Secretary.

Southwestern Meeting on Nuclear Medicine.—The fourth annual meeting of the Southwestern Society of Nuclear Medicine will be held in the Roosevelt Hotel, New Orleans, March 14-15, under the presidency of Dr. Herbert C. Allen Jr., Houston, Texas. The program includes 17 scheduled papers and three panel discussions with the following titles and moderators:

Some Aspects of Isotope Use in Studies of Electrolyte Metabolism, Dr. Sam A. Threefoot, New Orleans, La.
Medical Management in Radiation Accident Cases, John Hidalgo, M.S., New Orleans, La.
Symposium on Scintillation Scanning, Dr. Herbert C. Allen Jr., Houston, Texas.

The business meeting and dinner are planned for the evening of March 14. For information write Dr. Samuel B. Nadler, 1520 Louisiana Ave., New Orleans 15, chairman of the program committee.

Proctology Meeting in New York City.—The 11th annual convention of the International Academy of Proctology will be held at The Plaza, New York City, April 5-9. The international, national, and local program committees are planning a seminar on practical techniques for office and hospital. There will be special emphasis on anal and rectal panel presentations, and on newer treatment methods, as requested by those who attended the Mexico City meeting in 1958. Motion-picture demonstrations are planned. Members and nonmembers of the academy and their wives are invited to the banquet April 8. The Women's Auxiliary has planned a program for the wives and their guests. There is no fee for attendance at these teaching sessions of the academy. For information, write the International Academy of Proctology, 147-41 Sanford Ave., Flushing, N. Y., Dr. Alfred J. Cantor, Executive Secretary.

Allergists Meeting in San Francisco.—The 15th congress of the American College of Allergy will be held March 15-20 at the Mark Hopkins Hotel, San Francisco. A graduate instructional course in allergy will be conducted March 15-17. Dr. Merle W. Moore, president of the college, will speak at the general session March 18. On March 19 a panel discussion, "Repository Injection Treatment of Inhalant Allergy," will be moderated by Dr. Lawrence J. Halpin. Dr. Max Samter, president, American Academy of Allergy, will present "Semantics—and the Future of Allergy" the afternoon of March 19. Sectional sessions will be conducted March 20 under the following headings: Dermatologic Allergy, Psychosomatic Medicine, Technology, and Pediatric Allergy. Tours, movie sessions, and exhibits are planned. For information write the American College of Allergy, 2049 Broadway, Boulder, Colo.

Triological Society Meeting in Hot Springs, Virginia.—The American Laryngological, Rhinological, and Otological Society, Inc., "The Triological Society," will meet March 10-12 at the Homestead, Hot Springs, Va. A business meeting will precede each session. The presidential address will be given by Dr. Gordon D. Hoople, Syracuse, New York. Speakers on the program are as follows: Drs. George F. Reed, Boston; John J. O'Keefe, Philadelphia; Robert E. Boswell, Dayton, Ohio; John F. Daly and Samuel Rosen, New York City; Walter E. Heck, Robert C. McNaught, Leonard G. Dobson, and Francis S. Greenspan, San Francisco, Calif.; Victor R. Alfaro, Washington, D. C.; George E. Shambaugh Jr. and Henry B. Perlman, Chicago; Lester A. Brown, Atlanta, Ga.; Miles L. Lewis Jr., New Orleans; Bruce Proctor, Detroit; Maurice Schiff, Oakland, Calif.; Clair M. Kos, Iowa City; and Howard P. House, Los Angeles. For information write C. Stewart Nash, 708 Medical Arts Building, Rochester 7, New York, Secretary.

Nigerian Physician Wins Rehabilitation Award.—The appointment of Dr. Badejo O. Adebonojo of Nigeria as the recipient of the "Betsey Barton Fellowship" in Rehabilitation of the World Rehabilitation Fund has been announced by the fund's president, Dr. Howard A. Rusk. The "Betsey Barton Fellow" in rehabilitation, to provide advanced training in rehabilitation in the United States for a physician from Africa or Asia, was made possible by a grant to the World Rehabilitation Fund from the Aaron E. Norman Fund, Inc. The fellowship was named in honor of Miss Betsey Barton "because of her leadership in extending and expanding rehabilitation services throughout the world." Miss Barton, who is a paraplegic, is a member of the Board of Directors of the National Paraplegia Foundation, Inc., and of the board of Trustees of the Institute for the Crippled and Disabled. Dr. Adebonojo will begin his advanced training March 1 at the Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center, New York City. The World Rehabilitation Fund, Inc., is a nonprofit organization supported by American industry, foundations, and individuals to assist in the international development of rehabilitation services for the physically handicapped.

Annual Southern Conference on Gerontology.—"Society and the Health of Older People" will be the theme of the ninth annual Southern Conference on Gerontology, to be held on the campus of the University of Florida, Gainesville, March 19-20. The program will deal primarily with "psychosocial aspects of wellness and illness." Sessions will be devoted to the challenge of optimum health in old age; anthropological, sociological, and psychological aspects of health; social factors in the health of the elderly as seen from the standpoint of the physician, the social worker, the nurse, and the biologist; and public and professional aspects of the health care of the aged. Participants include Dr. Halbert L. Dunn, chief, National Office of Vital Statistics; Marion T. Loftin, Ph.D., of Mississippi State College; Ethel Shanas, Ph.D., of the University of Chicago; Robert W. Kleemeier, Ph.D., of Washington University (St. Louis); Carter C. Osterbind, Ph.D., of the University of Florida; Dr. Samuel Gertman, of the University of Miami; and Dr. Albert V. Hardy, of the Florida State Board of Health. For information write Irving L. Webber, Ph.D., Institute of Gerontology, Peabody Hall, University of Florida, Gainesville, or Robert L. Fairing, Ph.D., General Extension Division, Gainesville. The meetings are sponsored by the Institute and the General Extension Division of Florida.

Youth Fitness Week.—A Presidential Proclamation designating May 3-9, 1959, as National Youth Fitness Week, reads as follows:

WHEREAS the ongoing strength of our Nation depends upon health of our young people; and

WHEREAS we must always strive to improve the fitness of our youth by determined and coordinated efforts; and

WHEREAS, in this challenging world, it is essential that our young people recognize their obligation to themselves, to their families, and to the Nation, to endeavor to keep themselves mentally, emotionally, spiritually, socially, and physically fit; and

WHEREAS the President's Council on Youth Fitness has recommended that a National Youth Fitness Week be designated:

NOW, THEREFORE, I, DWIGHT D. EISENHOWER, President of the United States of America, do hereby proclaim the week beginning May 3, 1959, as National Youth Fitness Week.

I request officials of the Government, and I urge parents, young people, and interested local and national organizations, to use all appropriate means during that week to promote programs and activities demonstrating the importance of youth fitness to the end that we may assure the continuing strength and wellbeing of our people.

In Witness Whereof, I have hereunto set my hand and caused the Seal of the United States of America to be affixed.

Done at the City of Washington this thirty-first day of January in the year of our Lord nineteen hundred and fifty-nine and of the Independence of the United States of America the one hundred and eighty-third.

Dwight D. Eisenhower

Report on Age and Mortality.—Despite the marked progress made in reducing mortality in the United States, 40% of all deaths still occur at ages under 65, according to statisticians of the Metropolitan Life Insurance Company. More than 670,000 deaths a year are at ages under 65. Included were about 108,000 babies less than a year old and more than 400,000 people in the 45-64 year age bracket. Most deaths among infants are associated with pathological conditions existing prior to birth or with the hazards of the birth process, the statisticians point out. Three-fifths of the mortality results from "diseases of early infancy," a category comprising mainly deaths attributed to premature birth, postnatal asphyxia, and injuries at birth. Congenital malformation accounts for an additional 14% of infant deaths. In the mortality for the 1-24 age group, accidents are responsible for a greater number of deaths than all other causes combined, even among the girls. Among boys at these ages, motor vehicle accidents alone account for more than one-quarter of the deaths. In the 25-44 age group, the diseases of the heart, arteries, and kidneys account for nearly a third of the deaths among the males, with accidents a close second. Among women at these ages, cancer heads the list of causes of death. At ages 55-64 diseases of the heart, arteries, and kidneys account for nearly three-fifths of the deaths among men and for more than half the total among women. Second in rank is cancer, which accounts for 20% of the deaths among men and nearly 30% among women.

Education Foundation Has Record Campaign.—The 1958 campaign for the American Medical Education Foundation resulted in a record total of $1,120,044 plus interest, according to John W. Hedback, executive secretary of the Foundation. State and county AMEF committees raised the amount from physicians during the year. The grants to 85 medical schools were made at the 55th annual Congress on Medical Education and Licensure in Chicago, Feb. 7-10. The 1958 fund represents a 15% increase over 1957 totals. Thirty-five states reported increases, ranging from $9.06 (Nebraska) to $31,000 (New Jersey). The total dollar increase amounted to $148,000. Indiana, after one year as a dues-increase state, reported $30,600, for a total two and a half times that of a year ago. Alaska jumped from $125 in 1957 to $1,414.50 in 1958—an increase of 1,131%. Other spectacular climbs were made by Idaho (342%) and South Carolina (281%). Illinois physicians contributed $200,191, placing them first in the nation. California followed with $171,611. Both are dues-increase states. Arizona's 1958 total of $12,600 includes $1,000 from retail druggists. The amount stems from a program initiated late in the year through which druggists send gifts to AMEF in physicians' names in lieu of Christmas gifts. The plan was endorsed by the Arizona Retail Druggists Association. The Woman's Auxiliary to A. M. A. established a new record themselves with contributions of $126,200. Delaware, Maryland, Massachusetts, New York, Ohio, Texas, and Washington, D. C., all reported sizeable increases over 1957—ranging from $2,350 to $14,300 for an average of $6,000.

Contest for Paper on Gastroenterology Research.—The American College of Gastroenterology has announced the establishment of an award contest for the best unpublished paper on research in gastroenterology or an allied field. This award is to be known as the Henry G. Rudner Sr. Award, honoring Dr. Henry G. Rudner Sr., of Memphis, Tenn., chairman of the Research Committee of the American College of Gastroenterology and former chairman of the board of governors of the organization. This contest will be open to all those possessing the degree of doctor of medicine from a recognized medical school or university. All papers submitted must represent original work in gastroenterology, or an allied field, and must not have been previously published except for abstracts or short preliminary reports. It must not have been previously presented on the program of any scientific meeting. The papers may be on clinical or basic science; clinical papers must not be case records, but controlled clinical work. The length of a paper is no criterion for originality or value. All entries for the 1959 award must be typewritten in English, double-spaced on one side of the paper, and submitted in six copies. The award will be made at the annual convention banquet of the college, in Los Angeles, in September, 1959. The prize will be an award of $750 plus an additional $250 for traveling expenses. The paper selected for an award becomes the property of the American College of Gastroenterology and the decision of the judges will be final. All entries must be received no later than June 1 and should be addressed to: The Research Committee, American College of Gastroenterology, 33 W. 60th St., New York 23.

Committee on Bioastronautics.—The National Academy of Sciences–National Research Council announced the organization of the Armed Forces–National Research Council Committee on Bio-Astronautics. The committee will advise the Armed Forces, on their request, in any matter concerning the biological or medical aspects of space exploration. Policy decisions and the programming of activities within the committee will be the responsibility of an executive council to which the following scientists have been appointed by Dr. Detlev W. Bronk, president of the Academy–Research Council: chairman, Otto H. Schmitt, Ph.D., department of physics, University of Minnesota; vice-chairman, Melvin Calvin, Ph.D., department of chemistry, University of California, Berkeley; Howard J. Curtis, Ph.D., department of biology, Brookhaven National Laboratory; Paul M. Fitts, Ph.D., department of psychology, University of Michigan; Brig. Gen. Donald D. Flickinger, directorate of life sciences, Air Research and Development Command; Dr. John D. French, department of anatomy, University of California Medical Center, Los Angeles; Capt. Charles F. Gell, Office of Naval Research; James D. Hardy, Ph.D., U. S. Naval Air Development Center, Johnsville, Pa.; and Col. Robert H. Holmes, Research and Development Command, Office of the Surgeon General, Department of the Army. The full Committee on Bio-Astronautics—which will consist of more than 100 members, of whom at least half will be nominees of the Armed Forces—will serve as a conference or forum of active investigators, meeting periodically to review scientific and technical problems, exchange information, and establish liaison between investigators with allied interests. Administrative responsibility for the committee has been vested within the Academy–Research Council's Division of Medical Sciences, whose chairman is R. Keith Cannan, ScD. Acting executive secretary to the committee is Dr. Sam F. Seeley.

Directory of Blood Facilities.—A directory and description of blood facilities and services has been released by the Joint Blood Council, a nonprofit national organization with headquarters in Washington, D. C. It shows the location of facilities, the extent of their operations, how they are organized, what specific services they offer, and other information of importance to physicians, hospitals, and any person or organization interested in blood and its derivatives. The directory is based on data obtained from a questionnaire sent to all known blood banks, hospitals, and clinics that offer blood-handling services. The questionnaire was sent to 3,150 institutions and 2,202 replied. Those that failed to return the information will have an opportunity to supply it for future directories. The directory will be distributed free by the council to all institutions and organizations that participated in its preparation, according to Dr. Frank E. Wilson, executive vice-president. Others may obtain it at the cost price of $1.50 each from the Joint Blood Council headquarters, 1832 M Street, N. W., Washington 6, D. C. The council was formed three years ago by the American Association of Blood Banks, the American Hospital Association, the American Medical Association, the American National Red Cross, and the American Society of Clinical Pathologists "to establish a national blood program in order to assure an adequate supply of blood and blood derivatives to the civilian and military population at all times of peace or emergency and to take all appropriate action in connection therewith." Information includes the following: (1) Of the facilities listed, 1,832 administer whole blood. Also, 1,287 administer plasma, 1,021 serum albumin, 994 packed red blood cells, and 311 platelets, with many of the facilities engaging in a number of these activities. (2) Artery banks are maintained by 116, eye banks by 36, bone banks by 200, skin banks by 24, and mother's milk banks by 20. (3) A total of 1,325 blood banks store whole blood, record donor histories, and have as their primary purpose the recruitment of donors and complete laboratory blood processing. (4) Two out of every three organizations listed have no reciprocity system for the exchange or resupply of blood. Of the remaining one-third, 470 use the American Red Cross system, 240 that of the American Association of Blood Banks, and 110 use both systems. Dr. Leonard W. Larson is president of the Joint Blood Council.

FOREIGN

International Course on Tomography.—The fourth International Course on Tomography will be held at the Radiology Institute, University of Genoa, Italy, under the direction of Prof. Alessandro Vallebona. This course will last eight days and deal particularly with the recent progresses in tomographical methods. The period September-October, 1959 has been chosen for this meeting. All lectures, while read in the original language, shall be contemporarily translated into Italian, French, English, German, and Spanish. All interested physicians are advised to write Prof. Neopolo Macarini, General Secretary, Instituto di Radiologia della Universita-Ospedale San Martino, Genova, Italia, for information.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Stations around the world, Feb. 17. Deadline for foreign applications was Nov. 17. The following examination will be held Sept. 22 with application deadline of June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arkansas:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

Connecticut:* *Regular. Examination.* Hartford, March 10-12. Acting Sec., Dr. Stanley B. Weld, 160 St. Ronan St., New Haven.

Florida:* *Examination.* Miami Beach, June 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Michigan:* *Examination.* Ann Arbor and Detroit, June 8-10. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

Minnesota:* *Reciprocity.* St. Paul, February. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul.

Montana: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 15-17. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Jersey: *Examination.* Trenton, June 16-19. Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton 8.

New Mexico:* *Examination and Reciprocity.* Sante Fe, May 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

North Carolina: *Examination.* June Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Written.* Portland, Apr. 17-19. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

South Carolina: *Reciprocity.* Columbia, May 12; *Examination.* Columbia, June 23-24. Sec., Dr. H. E. Jervey, Jr., 1829 Blanding St., Columbia.

Texas:* *Examination and Reciprocity.* Fort Worth, June 22-24. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 8-10. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination.* Richmond, June 18-20. *Endorsement.* Richmond, June 17. Address: Board of Medical Examiners, 631 First St., S. W., Roanoke.

Wisconsin:* *Written.* Milwaukee, July 14-16. *Reciprocity.* Madison, April 17 and Milwaukee, July 15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, June 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

District of Columbia: *Examination.* Washington, May 18-19. Address: Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N. W., Washington.

Florida: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, April 14. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Examination.* Kansas City, June. Sec., Dr. L. C. Heckert, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, May 8-9. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Nebraska: *Examination.* Omaha, May 5-6. Director, Mr. R. K. Kirkman, Bureau of Examining Boards, 1009 State Capitol Bldg., Lincoln.

Oklahoma: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon: *Written.* Mar. 7. Sec., Dr. Earl M. Pallett, Box 5175, Eugene.

Tennessee: *Examination.* Memphis, Mar. 25-26. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* Austin, Galveston, Houston, Apr. 17-18. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, April 4. Final date for filing application is March 27. Milwaukee, June 6. Final date for final application is May 29. Sec., Mr. W. H. Barber, 621 Ransom St., Ripon.

BRAZIL

Blood Groups Among Brazilian Indians.—Several studies were made of blood groups among Brazilian Indians. In the State of Paraná, Dr. L. Fernandes found that of 77 Caingangues Indians 81.6% belonged to blood group O, 13.1% to group B, and 5.3% to group A. Among 119 Bororós and 237 Caiuiás Indians in the state of Mato Grosso, Dr. L. Ribeiro and co-workers observed the same predominance of group O. More recently a study of 71 Indians living at Porto Capitão Vasconcelos in the state of Amazonas by Dr. G. M. Leite and co-workers of the University of São Paulo (*Revista paulista de medicina*, vol. 53, November, 1958) showed that all belonged to group O. The MN factors were distributed as follows: M, 46%; N, 4%; and MN, 50%. All were Rh positive.

Fungi in Gallbladder.—At the Institute of Mycology in Recife, Dr. A. C. Batista and co-workers (*Revista da Associacão médica brasileira*, vol. 4, October, 1958) found Candida and Cryptococcus in the bile of 21 of 33 patients with cholecystitis. They examined 109 samples of bile. Differences between microscopic results and the ones with culture mediums were ascribed to the use of tetracycline in the mediums to prevent bacterial growth. These findings may have a bearing on the etiology of cholelithiasis and on some allergic manifestations of unknown origin.

Asthma Treated with Hypnosis.—Dr. A. C. M. Passos, of the Escola Paulista de Medicina of São Paulo (*Revista brasileira de tuberculose*, vol. 26, December, 1958), induced hypnosis in three patients with asthma. One was treated by prolonged suggested sleep (19 hours a day) for 60 days, with excellent result. The others were treated by direct suggestion of relaxation for 30 to 60 min. They also obtained favorable results.

GERMANY

Diagnostic Errors in Bronchial Carcinoma.—In some patients it is difficult to diagnose bronchial carcinoma correctly, especially early in the course of the disease. For this reason an exploratory thoracotomy is often necessary. Becker and Knothe (*Thoraxchirurgie* 6:235, 1958) investigated a series of 443 patients who were subjected to thoracotomy and whose conditions had been diagnosed as bronchial carcinoma at the surgical clinic of Giessen University. There were 18 diagnostic errors among 256 resections (7.1%) and 4 among 190 thoracotomies (2.1%). Ten patients had chronic pneumonitis, six tuberculosis, three a benign bronchial tumor, one Hodgkin's disease, and in two the diagnosis could not be determined. As most of these conditions required surgical treatment little harm was done by performing the thoracotomy, but in some of the patients a correct diagnosis would have prevented resection of a whole lobe. In six patients the wrong diagnosis was due to preoperative and/or intraoperative histological examination. In many cases the cause of histological diagnostic errors was that too little material was obtained for examination. Because of these diagnostic errors, sputum examination and/or bronchoscopy are no longer relied on and a pulmonary biopsy specimen should be obtained for final verification of the diagnosis.

Isoniazid Resistance.—Along with the decrease in mortality from pulmonary tuberculosis, an increase in the number of incurable cases of open tuberculosis has been noted. To reduce the risk that such patients constitute as potential sources of infection, it is necessary to expand control programs insofar as possible. The possibility of reducing the virulence of the Mycobacterium tuberculosis discharged by these people is being explored. The virulence of highly isoniazid-resistant tubercle bacilli is usually greatly diminished. H. Bierschenk (*Ztschr. Tuberk.* 111:159, 1958) reporting on a study of 37 patients with open tuberculosis, 13 of whom had tubercle bacilli of normal sensitivity in their sputums, concluded that isoniazid-resistant tubercle bacilli rarely cause disease unless the infecting dose is extremely high or the patient is particularly susceptible. Continuous administration of isoniazid reduces the danger of the nonisolated patient with open incurable tuberculosis as a source of infection. The time required and degree of the decrease of infectivity cannot be predicted but the time is probably several months.

Cancer in Childhood.—Among the causes of death in childhood, infectious diseases have ceased to predominate. Fatal accidents now hold first place. They are followed in order of frequency, in all civilized countries, by malignant disease, including leukemia, lymphosarcomatoses, carcinoma, and sarcoma. In the state of North Rhine–Westphalia, the number of deaths from malignant disease has

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

superseded that from tuberculosis. In children aged 6 to 15 malignant disease ranks higher than pneumonia and tuberculosis combined. In the whole Federal Republic, this marked increase in mortality from tumors and leukemia has been observed among infants and children since 1951. It is only partly relative, i. e., explained by the decreasing mortality from infectious diseases. E. F. Hugh (*Ärztl. Wschr.* 13:990, 1958) surveyed the tumor localizations of patients at the children's clinic of the medical academy at Düsseldorf and found in the order of descending frequency: leukemia and tumors of the brain, kidney, soft tissues, eye, and bones. Some of the most frequent tumors of children were distinguished from those of adults by being genuinely embryonal. Preventive measures recommended include the exclusion of all carcinogenic agents from both mother and child, and avoidance of exposure of infants to x-rays. It is not sensible to protect the fetus in utero from x-rays only to expose the infant after birth to unnecessary radiologic examinations.

INDIA

Lung Surgery.—P. Singh (*Indian Journal of Surgery*, vol. 20, October, 1958) analyzed a series of 238 patients subjected to lung surgery. In most of them the pulse rate was well stabilized preoperatively. A few because of a high pulse rate had to be operated on in two stages at an interval of two to three days and did well even when the preoperative pulse rate was 100 to 140. Some had a high temperature at the time of operation and these were also operated on in two stages. Breath-holding time was another preoperative criterion, a patient with a breath-holding time of 45 seconds or more being considered an excellent risk; one with 30 to 45 seconds, a good risk; and one with less than 30 seconds, a poor risk. Patients with a breath-holding time of over 30 seconds and vital capacity of over 2 liters usually behaved well during the operation. An exercise tolerance test was made on 37 patients and served as a useful guide to physical status. A hemoglobin level of 10 to 15 Gm. was considered favorable, although occasionally patients with lower values had to be operated on. Most of the patients before operation had a sedimentation rate of less than 20 mm.

In most patients anesthesia was induced with thiopental and maintained with nitrous oxide, oxygen, and ether. Tracheal obstruction by secretions was not common as most of the patients were well prepared by regular postural drainage but some required bronchoscopic aspiration before anesthesia. Postoperative complications, besides shock and hemorrhage, included subcutaneous emphysema, mediastinal emphysema, pneumothorax, contralateral spontaneous pneumothorax, mediastinal displacement, paradoxical respiration, tachycardia, arrhythmias, retained secretions, pulmonary edema, atelectasis, laryngotracheal bronchitis, pulmonary infections, hydrothorax, and acute dilatation of the stomach. There were 10 deaths in the series, 7 due to shock, 1 due to anuria, and 2 unexplained.

Sulfamethoxypyridazine.—P. G. Kamath and coworkers (*Indian Journal of Medical Sciences*, vol. 12, November, 1958) treated 28 patients who had acute urinary and respiratory tract infections with sulfamethoxypyridazine, a long-acting sulfonamide. Only those who were not previously treated by other sulfonamides or antibiotics were included. The drug was given orally, the common dosage schedule being 1 Gm. as initial dose, followed by 0.5 Gm. daily. In severe cases 2 Gm. was given initially, followed by 1 Gm. daily. The larger dosage was also used when there was no response to the lower dosage within two or three days. The duration of treatment varied from 4 to 16 days. A good response was observed in 21, a poor or no response in 3, and in 4 the drug had to be discontinued because of toxic effects. The series included 15 patients with lobar pneumonia, 12 of whom showed a good response. The fever subsided on an average within 32 hours and the cough and pain in the chest subsided within three or four days. Of the three who failed to respond, two developed acute mania, one on the second day and one on the third day, and one developed hemorrhage and oliguria. There were six patients with bronchitis, all of whom showed a good response. One patient in this group complained of mild headache.

Of the four patients who had urinary tract infection with Escherichia coli or Proteus vulgaris, only one patient suffering from pyelitis due to P. vulgaris responded to the drug, the fever subsiding in six days and the pyuria showing a decrease. The urine cleared completely after 14 days, at which time urine culture was negative. The other three showed no improvement even after administration of the drug for 12 days. Of the remaining three patients one had a congenital cystic lung, one bronchiectasis, and one bacillary dysentery. The last two responded well but the first, after an initial improvement, developed acute delirium on the third day and this form of treatment was stopped. The clinical results of this drug in infections of respiratory tract were comparable to those with sulfadiazine. The number of pneumonia patients developing psychosis during treatment was, however, alarming.

Parekh and Adiga in the same journal reported the use of this drug in a series of 84 patients and 40 normal controls. Eight of the patients developed psychotic manifestations but the severity of infection could not be held responsible for these symptoms. Two had received only small doses of the drug and the duration of therapy was short.

Ony one patient gave a family history of mental illness. The toxic effects were attributed to the presence of a pyridine and a methyl group in the drug and the occurrence of psychosis in none of the controls suggested the possibility of the anoxia occurring in pneumonia having some relation to the toxicity of the drug.

Bone and Joint Lesions in Smallpox.—The *Indian Journal of Surgery* (vol. 20, October, 1958) contained a study of 10 subacute cases of smallpox arthritis uncomplicated by sinus formation. Biopsies of bone, muscle, joint capsule, and synovial membrane were performed to determine the kind of lesions present. Fluid aspirated from the joints was cultured. Clinically these cases resembled those of pyogenic arthritis except for absence of fever. Bilateral involvement and affection of elbow joints were common findings. Cases coming one to two years after the attack of smallpox showed fibrous ankylosis, and those coming seven or eight years later showed disturbances of growth, although there was a surprising amount of movement in the affected parts. Bony ankylosis occurred only if there was secondary infection after sinus formation.

The radiologic features in the subacute stage resembled those of chronic pyogenic arthritis except that both contiguous ends of the bones forming the joint were involved. Cystic changes and subperiosteal bone formation without sequestrums and without marked necrosis and new bone formation were characteristic features. Both epiphysis and metaphysis were involved along with the joint, and isolated bone involvement was rare. Joint changes consisted of increase in joint space and erosion of articular ends with some periarticular soft tissue swelling. In late cases the joint space was diminished with deformed articular ends, and, in some, scalloped ends with widening of the joint space was noticed.

Cultures of aspirated material and of tissues removed at biopsy were sterile. The microscopic appearance of the bone resembled that of osteitis fibrosa with occasional round cell infiltration. Soft tissues such as muscle, synovial membrane, and fascia showed fibrosis, hemorrhage, and round cell infiltration. The purely osseous lesions improved with scraping and curettage. Partial excision was performed in the osteoarticular type when satisfactory movement was obtained in the elbow in one patient and in another this operation was a failure. Nonspecific protein therapy and active use in a late case caused improvement in the range of movement. Eight early cases with swollen and tense joints improved with splinting and rest. One patient with bony ankylosis was subjected to manipulation under anesthesia to improve the angle of ankylosis. During follow-up study of these cases, a gradual improvement in the range of movements without any recurrence of inflammation was noticed. Deformities due to epiphysial damage tended to increase during the growth period requiring osteotomy in one patient for correction of valgus deformity at the knee joint.

Auxiliary Nursing.—A brighter future for the auxiliary nurse and better training for this type of health worker were called for at the 12-nation conference of auxiliary nursing sponsored by World Health Organization in December in New Delhi. It was suggested that local nursing school committees be set up to meet the needs of health services by improving local recruitment. The main purpose of such committees would be to inform the public about nursing training and services and to make living and service conditions of nursing workers attractive. At ministry level a nursing board or council would be able to encourage recruitment in the state or country as a whole. One group suggested that the registration of auxiliary nurses was desirable. Every auxiliary nurse should receive basic training to prepare her to act as an assistant nurse. Such assistant nurses could be employed in institutions where day-to-day supervision by trained nurses was available. For workers to be assigned to such specialized fields as tuberculosis, a further period of training would be necessary.

Health Aspects of Radiation.—A new step towards establishing India as a training center for southeastern Asian workers in the health aspects of radiation and atomic energy was taken in November when about 20 students from three southeastern Asian countries began a five-week course in health physics in Bombay. There were also four participants from the western Pacific region. This course is designed for physicists who will serve as supervisors and instructors in radiation protection. It is sponsored by the Indian Department of Atomic Energy and the World Health Organization with the cooperation of the Atomic Energy Commission of the United States.

Fractures of the Neck of the Femur.—Bhansali and Dholakia treated 30 patients with fracture of the true neck of the femur, their ages varying from just below 20 to 80 years. Three had valgus and 27 had varus fractures. The injury responsible for most of the fractures was an accidental fall while walking, running, or alighting from a train. The method of treatment depended on the type of fracture as seen radiologically, the duration of the fracture, the presence or absence of complications, the age of the patient, and the economic circumstances. The three patients with the valgus fractures were treated with simple bed rest, the limb being kept in a neutral position with the help of sandbags for three months. Smith-Peterson nailing was performed in 16 patients, in 5 of whom secondary operations were required. The shortest time between injury and operation was 2 and the longest 30 days. A plaster boot with a wooden board incorporated in its posterior part was applied immediately after the nailing to keep the limb in a position of internal rotation. Antibiotics were given routinely to all patients. Static quadriceps exercises were started on the same day or the next. On the third day the knee on the affected side was moved after turning the patient on the sound side. The patient was made to sit up in bed on the 4th or 5th day and the plaster boot was removed on the 12th to 14th day. Weight-bearing on the affected side was not allowed till there was radiologic evidence of sound bony union. There were three deaths in this series.

Fibrocongestive Splenomegaly.—Goyal and Gupta (*Current Medical Practice*, vol. 2, November, 1958) stated that the cause of Banti's disease is still controversial. Such factors as portal hypertension, chronic intoxication, and allergy have been considered. The authors studied the role of allergy in patients and experimental animals. Of 100 specimens from spleens removed at operation or autopsy, 37 showed the lesions of malaria, 30 formed a miscellaneous group, in 15 the enlargement was due to congestive heart failure, 13 showed varying degrees of fibrosis and congestion, and 5 showed the lesions of tropical splenomegaly. Spleens weighing 150 Gm. or more and showing evidence of fibrosis and congestion were classified as cases of Banti's disease. The liver and portal veins could be examined in 13 cases and only 6 of these showed evidence of portal obstruction; 2 were due to right-sided failure and 5 were from patients with such infections as bronchiectasis and tuberculosis. Thus all the cases of Banti's disease were not due to portal obstruction.

To determine the role of allergy in causing fibrocongestive splenomegaly, repeated injections of sheep serum were given to rabbits and repeated injections of tuberculin were given to a series of guinea pigs rendered allergic by previous injection of BCG vaccine. No splenomegaly developed in the rabbits although all spleens in rabbits that were killed from the 10th week onward showed fairly marked congestion and fibrosis. The spleen in guinea pigs also showed no enlargement, but there was microscopic evidence of congestion and a certain degree of reticuloendothelial hyperplasia with presence of hemosiderin in macrophages and extracellularly. Fibrosis was evident seven weeks after the commencement of the tuberculin injections. Thus allergy probably played some part although absence of marked enlargement indicated that it alone could not be responsible when there was no portal obstruction.

Surgical Ascariasis.—A. E. deSa (*Indian Journal of Child Health*, vol. 7, November, 1958) reported a series of 43 cases of roundworm obstruction in children. Surgical ascariasis was found to be the second largest cause of intestinal obstruction in children, the first being imperforate anus. The age of these patients varied between 2 and 10 years. Abdominal pain, vomiting, constipation, and fever were the most frequent symptoms, others being distention, drowsiness, and roundworms in vomitus and stools. The three most frequent signs of ascarideal obstruction in this series were the presence of a palpable and occasionally a visible mass, fever, and toxemia. The roundworm mass tended to be central, migrating from one part of the abdomen to another and frequently breaking up into two or more masses. The toxemia closely resembled that of typhoid with apathy, delirium, and muscular twitching. This was often dramatically relieved by intravenous administration of 25 cc. of 50% dextrose solution. The fever rarely exceeded 101 F (38.33 C). Increase in the eosinophilic count was not a reliable diagnostic sign.

Of the four types of obstruction attributed to ascaris (mechanical, spastic, ascarideal intussusception, and ascarideal volvulus), only the first two were observed in this series. There was only one case of spastic obstruction among the patients operated on, the walls of the ileum being powerfully contracted on a roundworm lying longitudinally inside so as to produce marked obstruction. The obstruction was commonly due to a firmly packed bolus of worms with the antimesenteric border showing areas of ischemia and gangrene when the lump was big. Proximal distention was never as pronounced as in other organic intestinal obstructions.

In one child a large number of the roundworms had found their way into the general peritoneal cavity through a pinpoint opening in the tip of the appendix, while in another no perforation was found in any part of the gastrointestinal tract, but the general peritoneal cavity was full of worms. Neither patient showed any peritoneal reaction, the edges of the perforation in the former being smooth, bleeding readily, and free of any fibrinous deposits. A chronic intraperitoneal abscess was occasionally seen after an indolent roundworm perforation. Thus one patient was brought in because of a liver abscess, the live roundworm wriggling out of the drainage opening after incision.

The author favored conservative treatment of these patients with operation only when the diagnosis is in doubt, perforation is diagnosed or suspected, distention is pronounced and progressive, or when conservative management has failed to relieve the distention and the general condition deteriorates. Conservative management includes correction of fluid and electrolyte imbalance by parenteral fluid administration, continuous gastric suction, daily saline enema, administration of atropine to counteract spasm, intravenous infusion of 25% dextrose solution for the toxemia and the administration of specific anthelmintics and suitable antibiotics. Of the 34 patients who were treated conservatively 28 were given santonin and calomel at night, followed by a simple enema next morning and a small dose of magnesium sulphate if it was found to be safe. This treatment was repeated once in one case and twice in another; six patients were given hetrazan syrup. The roundworms were generally passed within 24 hours and no purgation was required. The fact that purgation was not necessary with hetrazan as with santonin was a distinct advantage. In two patients the roundworms were passed soon after an intramuscular injection of 0.3 or 0.4 mg. of atropine. Penicillin and streptomycin were given routinely to combat associated infection. Six patients were operated on, three of whom died. Of the 34 treated conservatively, six died. In a patient with Meckel's diverticulum with a band obstruction roundworms crawled out of the umbilicus. This patient was operated on and died. The author stressed the inadvisability of early operation as most patients respond to conservative treatment.

Family Planning Program.—The Family Board requested that a tentative provision of $2,100,000 be made by the Government of India for the implementation of the Family Planning Program during the fiscal year 1959-1960. The main feature of this program would be an intensification of training and educational schemes, opening and maintenance of clinics, appointment of family planning education leaders, holding of orientation camps, free distribution of contraceptives through all primary health centers and medical institutions, strengthening of the institutions, and strengthening of the inspection organization and research. The number of clinics so far opened is 718. Against the target of 150 urban and 600 rural clinics by March, 1959, 171 urban and 400 rural clinics have been started. The state governments hope to open 151 additional rural clinics before March.

Leprosy.—Kelkar and Randive (*Indian Journal of Medical Sciences*, vol. 12, November, 1958) stated that many unsuccessful attempts have been made to transmit human leprosy to laboratory animals. They studied the role of such factors as age, repeated contact, and general resistance. Because children are known to be more susceptible to the disease than adults, newborn animals (75 rats, 36 hamsters, and 24 mice) were given multiple inoculations of human lepromatous material. The general resistance is on an average low in the tropics and subtropics where this disease is common. The body resistance of the laboratory animals was lowered by giving cortisone, feeding a diet deficient in vitamin B_1, sensitization with lepromin, administration of hyaluronidase, and exposure to x-rays. The inoculum consisted of a human lepromatous nodule and a suspension of human lepra bacilli. The nodule was inoculated subcutaneously and the suspension intramuscularly or intraperitoneally. Young adult rats thus inoculated served as controls. Both the groups were observed for 8 to 18 months.

The hamsters, 7 of which served as controls, were treated with varying doses of x-ray. Both the groups were observed for six months and killed when the animals looked emaciated. Of the 75 rats, 42 showed acid-fast granules in their tissue cells and a nonspecific cellular reaction which was mainly of a defensive inflammatory nature. The few organisms seen were in and around nerves, and a large number of acid-fast granules were seen in macrophages with diffuse pink cytoplasm. The control rats and those treated with cortisone and a vitamin B_1-deficient diet did not show any significant difference in their tissue reaction to repeated inoculation of human lepromatous material. The reaction, however, was more pronounced and a larger number of animals was affected when cortisone and a vitamin B_1-deficiency diet was given prior to inoculation.

The intraperitoneal inoculation of human lepra bacilli was found to be more effective than inoculation by any other route. There was a complete absence of tissue reaction in the mice treated with hyaluronidase or lepromin prior to inoculation. A study of tissue reactions in the hamsters showed evidence of survival, maintenance, and even proliferation of acid-fast organisms in over 50% of those in the irradiated group. Such evidence was absent in those treated with cortisone and in the controls. In young hamsters showing evidence of disease, the bacilli were liberated into the subcutaneous tissue after disintegration of the transplanted lepromatous nodule. Some bacilli were ingested by macrophages and others transported to regional axillary lymph nodes via lymphatics where they were again engulfed by macrophages and other cells of the reticuloendithelial system. The older hamsters so treated showed marked tissue damage. The tissue reactions suggested a progressive generalized infection. A dose of 100 r whole body irradiation given to young adult hamsters prior to inoculation of lepra bacilli thus proved to be a means of lowering body resistance of these animals to leprosy.

Anemia and Kwashiorkor.—Ismail and Chandra (*Indian Journal of Child Health*, vol. 7, November, 1958) treated 50 patients who had iron-deficiency anemia with intramuscular injections of an iron-dextran complex. These patients were divided into those in whom the iron deficiency was not associated with kwashiorkor (30) and those who had both conditions (20). The total dosage of elemental iron ranged from 700 to 1,200 mg. A 22-gauge needle of sufficient length to penetrate well beyond the superficial tissues and fat layers was used so as to ensure that the pool of iron was placed deeply into the muscle and to prevent it from leaking back into the subcutaneous tissues. The patients showed the usual clinical features of iron-deficiency anemia but koilonychia was rare. Glossitis, pigmentation, and dysphagia were also uncommon. In the first group 25 patients had a history of malnutrition, 13 of ascariasis, 8 of malaria, and 13 of repeated attacks of diarrhea. Three had active tuberculosis, one with tuberculous meningitis; seven had other respiratory infections, two urinary infections, and four hookworm infestation. In the second group 16 had a history of malnutrition, 12 of ascariasis, 8 of malaria, and 17 of repeated attacks of diarrhea. Two had tuberculosis and five had other respiratory infections. No patient was below one year of age.

The initial hemoglobin level in the first group varied from 20 to 50%. The average rise in the first week was 10% while over a four-week period the maximum rise was 60% and the minimum 10%. In the second group the initial hemoglobin level was 20 to 60% and the average rise during the first week was 8%, the maximum response being 30%. The red blood cell counts varied from 1.5 to 3 million in the first group and showed an average rise of 1.5 million in four weeks. The erythrocyte count and the PCV rose more rapidly than the hemoglobin level. In the second group, the initial erythrocyte count varied from 1 to 3.5 million and rose by 1.25 million after four weeks. Macrocytes and target cells were seen in the blood smears in many patients, indicating that the anemia in kwashiorkor may be of a mixed type. The bone marrow in the first group was typical of microcytic anemia with normoblastic reaction and in the second group the findings were those of a macronormoblastic reaction without any megaloblasts. The initial serum iron level showed great variation, the mean value being 50 mcg. per 100 ml.

After treatment, serum iron levels of 64 to 400 mcg. per 100 ml. and above were recorded. The total plasma proteins were low in both groups and the albumin/globulin ratio was altered. These changes were more marked in the second group but they were not related to the clinical features of the kwashiorkor or the severity of the anemia. Toxic reactions and local side-effects were almost absent. No allergic or pyrogenic reactions occurred. The advantages over oral iron therapy were that the absorption was not limited by the activity of the mucosal barrier, there was no likelihood of the treatment being suddenly discontinued, and a known quantity of iron could be given ensuring a rapid response.

Typhoid in Children.—Paul and Jatkar (*Indian Journal of Child Health*, vol. 7, November, 1958) found that of 2,000 admissions to the K. S. Children's Hospital, New Delhi, over a period of 21 months, 56 were for typhoid. Only two of these patients were between 1 and 2 years old. The highest incidence was between 5 and 9. The greatest number of cases were seen in June, July, and August. Two patients had had triple typhoid vaccination 1 and 2 years, respectively, prior to admission. A history of contact was available in six patients. The temperature did not follow any particular pattern, high, moderate, and low remittent grades being commoner than intermittent. Blood cultures positive for Salmonella typhosa were obtained in 37 cases. The Widal test was positive in titers of 1:60 to 1:3,200 in 25 patients. This test was not run on all patients with positive blood cultures and some who had positive blood cultures did not show a rise in titer.

The leukocyte count varied from a marked leukopenia to leukocytosis. A normal count was restored in those with leukopenia after treatment with chloramphenicol. The polymorphonuclear count varied from 40 to 80%. Three patients suffered a relapse which responded to a second course of chloramphenicol. There were four deaths, one due to encephalopathy, one to hepatitis, one to bronchopneumonia, and one to uncontrolled diarrhea. A full diet was given as soon as possible, usually within two or three days of admission, when the toxemia and fever abated. Three consecutive negative stool cultures at weekly intervals were considered necessary before discharging the patient. Typhoid fever is so common in India that it must be considered in all patients whose fever lasts more than three days.

Meprobamate in Tetanus.—Damany and Kamat (*Journal of the Indian Medical Association*, vol. 31, Nov. 16, 1958) stated that a fully conscious mind with the painful awareness of spasms probably increases the frequency of spasms and rigidity in tetanus. Tranquilization has therefore been considered essential in the treatment of this disease. The centrally acting sedatives commonly used have the danger of producing central depression. None of the muscle relaxants acting peripherally have proved uniformly successful and some of them also give rise to dangerous side-effects such as hemoglobinuria and pulmonary edema.

The authors therefore studied the usefulness of meprobamate which has both muscle relaxing and ataractic action, is orally effective, and has low toxicity. In their series of 66 patients with tetanus, 27 received the usual treatment with tetanus antitoxin, antibiotics, and sedation, and 39 received meprobamate in addition. The drug was given orally in six hourly doses of 800 mg. in adults till cure or death occurred. It was omitted temporarily in those who showed complications. Patients with a period of onset of spasms of less than 24 hours showed a higher mortality in both groups (50% in the first group and 33% in the second)' than those with the period of onset longer than 24 hours (19.1% in the first group and 18.5% in the second).

The duration of stay in hospital of those who survived varied from 8 to 26 days in both groups. Death in most of those who died occurred within 48 hours of admission. The percentage survival rate was a little better in the second group than in the first but meprobamate did not alter the course of the disease significantly. Whatever beneficial influence it had was seen only in mild and moderate types of cases, while the severer type was unaffected. Its tranquilizing and muscle relaxing action was apparently not strong enough to control the spasms and rigidity of tetanus. Another disadvantage was the prolonged period before its effects became manifest. No serious side-effects were attributed to the drug.

SWEDEN

Basophils in Asthma, Dermatitis, and Psoriasis.—The average basophil count in the peripheral blood of 20 patients with asthma, 30 with atopic dermatitis, and 22 with nonerythrodermic psoriasis was studied by Hans Rorsman (*Acta dermat.-venereol.* 38:175, 1958) to determine whether the decrease of basophils observed in urticaria was characteristic of allergic diseases or diseases of the skin. The control group consisted of 96 normal persons. None of the patients had an average count which significantly differed from the mean count of 44.8 ± 2.4 per cubic millimeter in the controls, but 5 patients with exfoliative erythroderma had an average of 95.6 basophils per cubic millimeter (range 42 to 214).

Exposure of Ruptured Lumbar Disks.—Carl Hirsch (*Acta orthop. scandinav.* 28:76, 1958) stated that hypotension keeps bleeding under control while disk surgery is in progress and offers a good view of the exposed area. It also protects against postoperative hematoma. This approach should limit the damage to important functional elements. By making the incision in the dorsal fascia lateral to the spinous processes and closing the wound with the spine flexed, postoperative tightness is less pronounced. Extensive disk removal protects against disk material being squeezed out when early weight-bearing is permitted. The patient is allowed out of bed after the operation. No physiotherapy, no support, and no fusion are needed.

Oxygen Saturation of the Cord Blood.—The oxygen saturation in the blood of the umbilical cord was measured with the Brinkman Haemoreflektor in 90 cases of cesarean section, of which 16 were classified as complicated and 74 as uncomplicated by Sjöstedt and Rooth (*Acta anæsth. scandinav.* 2:99, 1958). In uncomplicated cases in patients delivered under local anesthesia before the onset of pains, the oxygen saturation in the vein was 62.1%, and in the arteries 32.4%, i. e., the same values as in uncomplicated spontaneous deliveries. With the onset of pains the oxygen saturation decreased. Inhalation anesthesia with cyclopropane resulted in a marked depression of the oxygen saturation of the fetal blood and diminished the arteriovenous difference in the oxygen saturation, which led the authors to conclude that when local anesthesia can be used without risk to the mother this method is best for the infant.

Adrenocortical Hyperplasia.—A family consisting of normal parents, three healthy children, and three children with congenital hyperplasia of the adrenal cortex was studied clinically and analyses of their steroid excretion were made by G. Birke and coworkers (*Acta endocrinol.* 29:55, 1958). The parents and the three healthy children exhibited a normal excretion pattern of all steroid groups studied. One of the three affected children died at the age of 8 weeks before any steroid analysis could be undertaken. The other two children with adrenocortical hyperplasia showed a substantially increased excretion of both 17-ketosteroids and 17-hydroxycorticosteroids and pathologically altered excretion patterns. Of the individual 17-ketosteroids, androsterone was predominant and little, of any, etiocholanolone could be found. Of the individual 11-oxygenated 17-ketosteroids, 11-ketoandrosterone and 11β-hydroxyandrosterone were isolated and identified by infrared spectroscopy; 11-hydroxyetiocholanolone could not be detected. An indirect analysis of the 17-hydroxycorticosteroid pattern revealed the presence of huge amounts of pregnanetriol. Measurable amounts of tetrahydro-17α-hydroxycortexone tetrahydro-S) were also demonstrated in the urine. In neither of the two children was the excretion of the latter accompanied by hypertension. Tetrahydrocortisone and 11-ketopregnanetriol or cortolone were also identified, but no 11β-hydroxylated corticosteroids could be detected. The preoperative estrogen pattern was characterized in both patients by the complete absence of estriol. After bilateral adrenalectomy substantial amounts of estriol were detected in the urine in the case of a female pseudohermaphrodite, aged 15, with adrenocortical hyperplasia treated first by excision of the clitoris, then by bilateral subtotal adrenalectomy when cortisone in the dosage required for suppressing the adrenocortical secretion gave rise to mental symptoms.

Treatment of Salicylate Intoxications.—Celander and Haglund (*Acta anæsth. scandinav.* 2:123, 1958) used a combination of neuromuscular block, artificial respiration, and fluid and electrolyte therapy to treat severe salicylate intoxication. Of 20 patients treated 15 were under 6 years of age. A liberal supply of fluid and calories in the form of an intravenous dextrose solution was given while further clinical and laboratory analyses were being made. Controlled respiration combined with neuromuscular block when respiratory failure threatened was essential. Tubocurarine was used as the neuromuscular blocking agent. Tracheotomy was performed and artificial respiration maintained with the Gothia respirator. In no case was respirator treatment necessary for more than two days. During that time, the patient was allowed the necessary muscular rest, the acid-base disturbances were corrected, and salicylate excretion was achieved.

Myocardial Infarction.—Gunnar Biörck and co-workers (*Acta med. scandinav.* 162:81, 1958) made a follow-up study of 903 patients who were discharged from Malmö General Hospital after a myocardial infarction. The follow-up group represented 92.7% of those who were discharged home from a total of 1,530 patients hospitalized between 1935 and 1954. These patients were divided into 389 followed for more than five years, 246 followed for two to five years, and 268 followed for two years or less. Of the total series 63% survived a further 5 years, and 40% a further 10 years. If the acute mortality is included, the chance of a 5-year survival at the moment of hospitalization was 39%, and the chance of a 10-year survival was 23%. The survival rate decreases with increasing age at the moment of infarction, but in comparison to sex-age-specific death rates in the population, the prognosis for younger persons was worse than the prognosis for older people. There was a slight general tendency toward a better prognosis for the patients discharged in the latter part of the period investigated. This change was much smaller than the decrease in acute hospital mortality.

There was no obvious sex difference in the material, but in comparison to the sex-age-specific death rates of the population at large, there might be a slightly worse long-term prognosis for women in the ages over 60, which was, however, not statistically significant in the patients reported on. The prognosis for patients with a more severe infarct was not definitely worse than that for those with a mild infarct. Hypertension did not seem to affect the long-term prognosis. Patients with diabetes had a worse long-term prognosis than those without diabetes. Anticoagulant therapy during the acute stage of the infarct did not influence the long-term prognosis, but the interpretation of that finding must be guarded. There was some uncertainty connected with death certification, and while no detailed conclusions were made by the authors, they listed 41.9% dead of subsequent myocardial infarction, 31.9% of coronary heart disease with no evidence of acute myocardial infarction, 6.7% of cerebrovascular diseases, 9.0% of other cardiovascular diseases with 3.7% as malignancy, and 6.7% as miscellaneous for a total of 489 patients for whom such records were available.

Physical Work and Mitral Valvular Disease.—The physical working capacity and its relationships to heart volume, total amount of hemoglobin, and stroke volume was studied in 42 patients with mitral valvular disease, of whom 39 had isolated or predominant mitral stenosis and 3 had isolated or predominant mitral regurgitation. Operation was performed on 27 patients. The physical working capacity, estimated as the work performed continuously at a pulse rate of 170 per minute, was directly correlated to the stroke volume during work. In mitral stenosis the heart volume was large and the working capacity low in relation to the total amount of hemoglobin. A marked enlargement of the heart was usually combined with a high pulmonary vascular resistance. In some patients, however, in whom the pulmonary resistance was almost normal the enlargement might be partly due to left myocardial insufficiency. The degree of incapacity as judged from the exercise tolerance test showed good correlation to the degree of the hemodynamic disturbances. In the patients with mitral regurgitation the heart volume was large but the working capacity normal in relation to the total amount of hemoglobin and the pulmonary vascular resistance was normal, as reported by A. Holmgren and co-workers (*Acta med. scandinav.* 162:99, 1958).

Ulcerative Colitis and Cirrhosis of the Liver.—Ten patients who had ulcerative colitis with coexistent cirrhosis of the liver were reported by Lill Olhagen (*Acta med. scandinav.* 162:143, 1958). In eight, signs of cirrhosis preceded the ulcerative colitis or became manifest so early in the course of the colonic disorder that the condition could not have been the cause of the cirrhosis. Signs of portal hypertension were present in every instance. In view of the disappearance of intestinal symptoms after lienorenal anastomosis in two, it seemed likely that the portal stasis might have caused the ulcerative colitis. Mucosal changes in the colon might be brought about by long-standing venous stasis in the intestine leading to anoxia and impaired nutrition of the mucosa, a mechanism similar to that underlying the formation of varicose ulcers of the leg. No evidence of a causal connection between the two conditions could be shown and until wider experience is gained of operations designed to relieve portal stasis, the presence of ulcerative colitis strengthens rather than weakens the indications for operation.

Physiological Studies of Laborers.—Irma Åstrand (*Acta med. scandinav.* 162:155, 1958) examined 81 truck drivers at rest and during work; 12% had pathological or suspected pathological electrocardiographic tracings at rest and 19% had pathological and 33% suspected pathological tracings during work; 32% had high blood pressure at rest and 47% were considered as overweight. The vital capacity averaged 4.64 liters and the residual volume 1.99 liters or 30% of the total capacity. The ventilation per liter of oxygen intake at submaximal work was about 4 liters higher than for younger persons. The maximal pulmonary ventilation was, however, much lower; 72 of the subjects performed heavy muscular work and of these 2 had cramp-like pains in the precordium as the most troublesome symptom; 20 complained of dyspnea, 31 of local muscular fatigue, 6 of pains in the knee or hip, and the remaining 13 complained of being tired without any specific symptoms. None of the above-mentioned findings were highly correlated with maximal oxygen intake or maximal heart rate. The reason for the decreased physical work capacity could not be explained.

Diabetes and Portal Cirrhosis.—The case records from 108 patients with cirrhosis of the liver (67 men and 41 women) were reviewed by Ragnar Hed (*Acta med. scandinav.* 162:189, 1958) with particular attention to the presence of diabetes. The diagnosis of cirrhosis was verified in all cases at autopsy or by liver biopsy. Chronic alcoholism was present in 55.2% of the men and 4.8% of the women. Primary carcinoma of the liver was present in 20.9% of the men at autopsy and in 4.8% of the women. Diabetes was definitely present in 18 cases (12 men and 6 women). The diabetic incidence was 14.3% in the women and 17.6% in the men. Since these figures were higher than those for diabetes in the entire autopsy material during the same period, a relationship between cirrhosis of the liver and diabetes was assumed to exist. In seven further cases (six men and one woman) the fasting blood sugar level was significantly elevated. If these patients were included, the incidence of impaired sugar metabolism of diabetogenous type becomes 26.5% for the men and 16.7% for the women. The type of diabetes present in this series was comparable to that usually appearing first at from 40 to 60 years of age and occurring most commonly in women. In the present series, however, the diabetic incidence was higher in the men. In explanation of this phenomenon the author suggested that alcoholic cirrhosis was more frequently associated with impairment of carbohydrate metabolism of diabetogenous type than were other forms of cirrhosis.

Carbohydrate Metabolism in Chronic Alcoholism.—A series of 75 male alcoholics was investigated with a view to determining the incidence of disturbances of carbohydrate metabolism by Ragner Hed (*Acta med. scandinav.* 162:195, 1958). In 24 glucose and insulin tolerance tests and liver biopsy were done. Diabetogenous disorders of sugar metabolism were demonstrated in 12 of these, of which 10 showed cirrhosis and 2 a high-grade fatty liver. Four of these 12 patients had manifest diabetes and 8 only diabetogenous glucose tolerance curves. In many of these 8 patients the fasting blood sugar was also pathologically elevated on several occasions. In the intravenous insulin tolerance test relative insulin resistance was demonstrated in all 12. The results of the investigations in these 12 patients indicated a difference in degree only with respect to the diabetogenous sugar metabolism disturbance between the 4 with manifest diabetes and the 8 with only diabetogenous glucose tolerance curves. In 12 patients the glucose tolerance curves were of the nondiabetogenous type. In the intravenous insulin tolerance test the hypoglycemia appeared within the normal interval in all 12 patients. None of these had fully developed cirrhosis. Two types of hypoglycemia were observed—a transient form associated with an alcoholic debauch and a more chronic form. In the present series hypoglycemia was associated with the milder cases of liver degeneration and diabetogenous metabolic disorders in the patients with more pronounced hepatic lesions.

Cardiac Changes in Chronic Alcoholism.—Frederiksen and Hed (*Acta med. scandinav.* 162:203, 1958) made electrocardiograms of 121 male alcoholics aged from 20 to 40 years. In no case was hypertonia, vitium cordis, thyrotoxicosis, or inflammatory cardiac disease present. In 66 the ECG was entirely normal. In 36 the only abnormality was tachycardia above 95 per minute. In 19 others electrocardiographic changes were found as well. Four patients showed auricular fibrillation. In addition, three presented broad, notched P waves, which were also interpreted as due to auricular lesions. It therefore seemed conceivable that the auricle was one of the sites of predilection for cardiac lesions in chronic alcoholism. Isoelectric and diphasic T waves were observed in four and a broad QRS complex in two. Conduction times of only 0.10 occurred in three. Chronic alcoholism was probably the cause of the cardiac lesions in these patients. Whether vitamin B_1 or protein deficiency was the more important factor in causing the cardiac lesions could not be established.

Transfusion Reactions.—A survey was conducted at the St. Erik's Hospital in Stockholm into the incidence of reactions in conjunction with 6,899 transfusions by Olof Ramgren and co-workers (*Acta med. scandinav.* 162:211, 1958). The incidence was 6%. No hemolytic reactions due to serologic incompatibility occurred. The rate for febrile reactions was 3.55%, allergic reactions 1.20%, and other reactions 1.20%. The use of disposable transfusion sets brought down the febrile reaction rate by 50%. The reaction rate increased with the number of previous transfusions. Rouleaux formation in the pretransfusion sample increased the risk of reaction. The age of the blood was of no consequence to the reaction rate if administered within 14 days. If a patient had had a certain type of reaction after blood transfusion, an increased risk of reactions, and of the same type, might be expected on subsequent transfusions.

Thyrotoxic Myopathy and Polymyositis.—Four elderly women, two classified as having thyrotoxic myopathy and two as having polymyositis were described by Boström and Hed (*Acta med. scandinav.* 162:225, 1958). The clinical findings presented great similarities in all four, and were initially misinterpreted as changes due to age. The following facts should be kept in mind for a differential diagnosis between these two forms of myopathy in the older age groups. Thyrotoxicosis often presents few symptoms in elderly patients, and can easily be overlooked; thyrotoxic myopathy is therefore likely to be confused with other forms of myopathy. The basal metabolic rate and urinary excretion of creatine often exhibit pathological values in both myopathies, and therefore have no value in differential diagnosis. In thyrotoxic myopathy, large doses of methylthiouracil produced a marked decrease in creatinuria or its disappearance within about 10 days, and even before any improvement in the muscular weakness had occurred. In polymyositis, this drug had no effect on creatinuria. In thyrotoxic myopathy, the histological changes in the muscle were generally slight, whereas severe damage to the muscle was observed in polymyositis. Progressive muscular weakness in elderly patients, particularly if it is combined with loss of weight, should not be ascribed to the process of aging without a thorough analysis, because certain forms of myopathy are amenable to effective specific or symptomatic therapy.

UNITED KINGDOM

Treatment of Cerebral Neoplasms by Cooling.—General hypothermia for the treatment of malignant growths has been tried but abandoned because prolonged hypothermia can cause cardiac fibrillation. Rowbotham and co-workers (*Lancet* 1:12, 1959) devised a localized form of hypothermia for the treatment of cerebral neoplasms which they used on two patients with glioma and one with astrocytoma after tests had been made on excised human brains. Cooling was effected by a specially designed cannula, used in conjunction with a circulating pump, cooling coil, and circulating fluid reservoir. The cannula consisted of two concentric steel tubes, one for the delivery of cooling fluid and the other for its return to a reservoir. Before reaching the cannula the cooling fluid passed through a coil surrounded by a freezing mixture of solid carbon dioxide and acetone with a temperature of about –74 C. The temperature of the reservoir was kept at about –20 C. Tests on excised brains had shown that insertion of the cooling cannula enabled the temperature of the brain substance to be reduced locally to –20 C. The patients treated were beyond the aid of neurosurgery. Under general anesthesia the brain was exposed and the sterilized cannula inserted into the tumor. It was cooled to –20 C for 20 to 30 minutes. A core of solid frozen brain tissue 10 to 12 mm. in radius formed around the cannula, but brain tissue 2.0 to 2.5 cm. away from the cannula had a temperature of 30 C (86 F). The three patients recovered from the operation. It was shown that it is possible to freeze a local area of the brain without endangering life. One patient died later, another remained the same, and the mental condition of the third patient improved markedly.

Trials with Human Growth Hormone.—A panel appointed by the clinical endocrinology committee of the Medical Research Council investigated the action in man of growth hormone extracted from human pituitaries. Chemically this differs from ox growth hormone, which is inactive in man. Numerous pathologists throughout the United Kingdom cooperated by collecting human pituitaries from fresh cadavers. The acetone-dried glands were extracted with 0.3 M potassium chloride and repeatedly fractionated with alcohol and ammonium sulfate between pH 4.4 and 8.6. The final product was standardized against international standard ox growth hormone. From 10 to 30 mg. of the human growth hormone was given daily to two subjects without pituitary disease and to six with hypopituitarism. From two to eight days later increased nitrogen retention was observed, as shown by a fall in blood urea and urinary nitrogen levels. In addition there was retention of sodium, potassium, magnesium, phosphorus, and sometimes calcium. The amount of potassium, magnesium, and phosphate retained was only what would be anticipated for protein synthesis, calculated from the retention of nitrogen, but the amount of sodium was greatly in excess of this. A consistent rise in fasting blood sugar level was also observed.

Vitamin B_{12} Absorption.—By direct measurement of the distribution of radioactivity in the small intestine of patients given vitamin B_{12} labeled with cobalt-56, Booth and Mollin showed that the site of the absorption of the vitamin in man is the ileum (*Lancet* 1:18, 1959). An oral dose of 1 mcg. of vitamin B_{12} was labeled with 5 μc of Co^{56}. The absorption was studied in patients undergoing laparotomy by examining the distribution of radioactivity in the small intestine three hours after the oral dose was given. An end-window Geiger-Müller counter covered with sterile rubber sheeting and a towel was used to measure the radioactivity. Starting from the duodenojejunal flexure the activity was measured at successive portions of the small intestine down to the ileocecal valve. Absorption was maximum in the distal half or two-thirds of the ileum. This was confirmed by observations on vitamin B_{12} absorption in patients who had undergone resection or short-circuiting of the small intestine. Resection of the jejunum does not interfere with the absorption of the vitamin, but absorption is subnormal if more than about 7 ft. of ileum has been removed. This defect is not corrected by giving tetracyclines. Removal of the ileocecal valve does not interfere with the absorption of vitamin B_{12}. The authors suggested that the physiological absorption of vitamin B_{12} might, in man, be a definite function of the distal part of the small intestine which may contain a specific receptor mechanism for it. A congenital defect of the specific vitamin B_{12} receptor would explain the development of the pernicious anemia syndrome. The authors observed signs of vitamin B_{12} deficiency in patients who had undergone operations on the ileum. The onset of this deficiency was insidious and gradual. They considered that vitamin B_{12} should be given after all operations involving resection of the ileum.

Increase in Myopia.—Herbert Archer, an ophthalmologist of the Birmingham school health service, found more children in schools to be myopic than in previous years. He attributed this to the use and abuse of television. Unless people can be taught to ration the time spent viewing television myopia is likely to become commoner. Archer predicted that a large number of children would pass from the less serious types into the category of high myopia, which is the fourth largest cause of blindness.

Accuracy of Death Certificates.—A study on the accuracy of death certificates was included in the annual statistical review for 1957 (Statistical Review of England and Wales, Her Majesty's Stationery Office, 1958). Over a six-month period 10 large English hospitals arranged for a double death certificate to be issued for every patient dying in the hospital. One certificate was completed by a physician on clinical findings and the other by a pathologist after autopsy. The pathologists agreed with the physicians in 51% of cases, and to this were added another 28% in which the differences were technical rather than actual. Thus in about 80% of the deaths the cause as certified by the physician was confirmed by the pathologist. In 19% the latter found fresh evidence at autopsy that was denied the physician during life. This occurred mainly in the newborn and the aged. Cancer of the lung was underdiagnosed by the physicians, particularly in older patients. Of patients dying from this cause 30% were found to have unsuspected cancers at autopsy. It is evident that the death rate from cancer of the lung in Britain is even higher than it is reported to be. There was also disagreement between physicians and pathologists on the diagnosis of arteriosclerotic and coronary heart disease. They agreed on only 41% of cases, which corresponded closely to the 44% accuracy rate for myocardial infarction found by Paton at the Edinburgh Royal Infirmary. A number of cases mistaken for coronary disease by the physicians were in fact pulmonary embolism.

Carbon Monoxide Poisoning.—Recommendations made by the Medical Research Council (MRC) on the treatment of carbon monoxide poisoning have undergone revision. Three years ago the MRC issued a report stating that a carbon dioxide-oxygen mixture should not be used for the resuscitation of persons poisoned by carbon monoxide. The reason given at the time was that under the uncontrolled conditions of first-aid, carbon dioxide might accumulate to dangerous levels in the tissues. This argument was seriously challenged by experts in so far as carbon monoxide poisoning was concerned, on the grounds that the administration of an oxygen-carbon dioxide mixture increased the elimination of carbon monoxide and brought about a more rapid recovery. A special subcommittee was therefore set up by the MRC to consider the problem. As a result of experiments on animals and on human volunteers poisoned with carbon monoxide, it was concluded that the administration of a mixture of oxygen and carbon dioxide leads to a more rapid elimination of carbon monoxide from the blood than does oxygen alone. From this and clinical evidence the MRC subcommittee considers that on balance a mixture of 5% carbon dioxide in oxygen is more likely to facilitate recovery from carbon monoxide poisoning than oxygen alone, but that there is no advantage in increasing the amount of carbon dioxide beyond 5%.

Pleuropneumonia-like Organisms in Genital Infections.—Further evidence for the role of pleuropneumonia-like organisms (PPLO) in pathological conditions, particularly in nongonococcal urethritis (NGU) in men, was obtained by Klieneberger-Nobel (*Brit. M. J.* 1:19, 1959). The identification of these organisms is difficult as they can be detected only by culture. Electron microscopy was abandoned as a means of identification, as the appearances could not be correlated with cultural methods. Urine specimens and discharge or scrapings from the urethra were obtained from men with NGU and related conditions, and from the vagina, cervix, or urethra of women from venereal, gynecologic, and prenatal clinics. Patients with Reiter's syndrome and a number of partners of patients from venereal disease clinics were also examined. The sediment from urine specimens was used for culture. PPLO were found to be absent from the urine of 97% of healthy men examined. One had NGU and another was a symptomless carrier of the organisms. PPLO were completely absent from the urine of 43 prepuberal boys seen in the medical wards of a hospital. The discharges and scrapings from men from the venereal disease clinics were positive for PPLO in 25% of 201 patients. The highest number of positive results (48%) was obtained in those that had recently acquired NGU; 30% of the men with gonorrhea harbored PPLO. The organisms were present in the scrapings of 10% of the patients with Reiter's syndrome.

The incidence of PPLO was found to be much higher in the women patients; 56% of those attending venereal disease clinics were infected. In those with gonorrhea, whether treated with penicillin or not, nearly 90% carried the organisms in the urethra, vagina, or cervix. Surprisingly enough 23.5% of the pregnant women examined harbored PPLO in the cervix. The incidence in gynecologic patients of a London hospital was 17%. PPLO were not found in the synovial fluid of patients with Reiter's syndrome, and only rarely in the urethral discharge. This refutes the commonly held view that Reiter's syndrome and NGU have a common cause. The author's observations show that genital strains of PPLO are absent before puberty, and rare in healthy young men and women. They are associated with recently acquired urethritis in a high proportion of men suffering from NGU, and with cervicitis, vaginitis, and urethritis in women. They are often present in patients with gonococcic and trichomonal infections and are particularly likely to be transferred by sexual intercourse.

Spirochetal Rat Bite Fever.—Rat bite fever caused by infection with Spirillum minus is extremely rare in England, no case having been reported for over 30 years. Edmunds and Tilley described a case occurring in Edinburgh due to a mouse bite (*Lancet* 2:1211, 1958). No reference to mice as a source of infection in this country has been reported before. An 11-year-old boy was bitten by a mouse and one week later developed a severe headache and pyrexia. Two weeks after the bite the puncture marks were painful, swollen, and red, and large spots appeared on the backs of his arms and legs. The pyrexia persisted, with intermittent fever around 103 F. The conjunctivas were injected, the eyelids were swollen, and the patient had an intractable headache. Appetite and weight loss occurred and a moderate soft enlargement of the principal lymph nodes was noted. The presence of Sp. minus was demonstrated by inoculation of mice and guinea pigs with the boy's blood. Large doses of penicillin were given. Although there is a widespread belief that mice are harmless, the risk to those handling them in the laboratory and during disinfestation should be more generally known.

Oral Treatment of Ringworm.—It was shown by Gentles that guinea pigs experimentally infected with Microsporon canis and Trichophyton mentagrophytes quickly responded to small oral doses of the antibiotic griseofulvin, which was isolated from Penicillium griseofulvum (*Nature* 182:476, 1958). The antibiotic is evidently absorbed and secreted into the dermis, as it was found by Gentles in the hair of treated animals. Williams and co-workers gave the antibiotic in oral doses of 0.5 Gm. four times a day to nine patients with clinical Trichophyton rubrum infection of the skin or nails and one with Microsporon audouini infection of the scalp (*Lancet* 2:1212, 1958). No local treatment was given. The antibiotic caused rapid relief of itching, growth of infected nails, loss of hyperkeratosis, and disappearance of the fungus from nail scrapings. In the one patient with ringworm of the scalp, the hair did not fluoresce under Wood's light three weeks after beginning treatment. The toxicity of griseofulvin is low and no side-effects were observed. These preliminary results support the hope that griseofulvin may be of use in the oral treatment of ringworm.

Surplus Women Declining.—For many years there have been more women than men in Britain. If the present trend continues and there are no more wars there will soon be as many men as women, according to the Registrar General's report, which states that the long-continued increase in the ratio of women to men, which started in 1821, or earlier, has now ended. In the last century, although from 40 to 50 more boys were born for every 1,000 girls, there was an excess of females over males because of the higher death rates for boys. About 60 more boys are now born for every 1,000 girls, but the death rate of boys is falling. At the last census women were still in the majority—1,082 to every 1,000 men. The report states that divorced women outnumber divorced men 130,000 to 79,000, because more men than women marry again. There are 2,319,000 widows, but only 739,000 widowers. This is attributed to the fact that women, particularly married women, live longer than men.

Antibiotics and the Common Cold.—In a letter to the *Lancet* Professor Garrod deprecates the use of chloramphenicol and other antibiotics, which have recently been recommended for the prevention of complications, in the treatment of the common cold. His chief reason for proscribing chloramphenicol is because it is known to cause bone marrow damage, and therefore its use is unjustified for trivial purposes. If an antibiotic must be used for the treatment of colds it should be penicillin, which is cheaper, safer, and can be used in the form of a spray, snuff, or pastille, but Garrod objects even to this form of treatment as it may lead to sensitization. If all common colds were generally treated by antibiotics it would add $315,000,000 to the annual drug bill of the nation.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Periarteritis Nodosa: Review. P. Bro-Rasmussen. Ugesk. laeger 120:1481-1489 (Nov. 6) 1958 (In Danish) [Copenhagen].

During the last 10 years 17 patients with periarteritis nodosa were admitted in the Rigshospitalet in Copenhagen. Of the 9 patients in whom diagnosis was made during life, 7 are living from 6 months to 9 years after the diagnosis. Periarteritis nodosa is counted among the collagen diseases, which also include chronic polyarthritis, lupus erythematosus disseminatus, thrombotic thrombocytopenic purpura, scleroderma, polymyositis, and dermatomyositis. Morphologically, all are characterized by marked changes in the connective tissue. Periarteritis nodosa occurs most frequently between the ages of 20 and 40 years and is seen more often in men than in women. The picture is polymorphic. Long-continued fluctuating fever is the main symptom. The frequency of admissions and the number of diagnoses made in life support the concept that the disease is increasing in frequency. Periarteritis nodosa should be considered in unusual combination of symptoms and in vague progressive cases, with fever, muscular asthenia, and loss of weight. The diagnosis is supported by information on allergic manifestations, hypersedimentation, hypergammaglobulinemia, transient electrocardiographic changes, and transient roentgenologic pulmonary changes. Only skin and muscle biopsies afford certain diagnosis. The treatment consists of the administration of 11-oxysteroids and is otherwise symptomatic. The prognosis is unfavorable. There seems, however, to be a tendency to remission in most cases in which the viscera are not involved. The disease may have an acute course with fatal outcome; the course may also be insidious and protracted or show remissions and acerbations with increasing symptoms of ischemic lesions of the different organs.

Negative L. E.-Cell Phenomenon in True Systemic Lupus Erythematosus. P. Formijne and F. van Soeren. Lancet 2:1206-1207 (Dec. 6) 1958 [London].

The authors report on a 53-year-old man with the typical aspect of systemic lupus erythematosus, in whom the L. E.-cell test gave completely negative results. Further immunological investigation showed that the Wassermann test could not be *carried out, owing to anticomplementary activity* of the patient's serum. It was then considered that a connection might exist between this activity and the negative L. E.-cell phenomenon. When excess normal fresh human complement was added to the patient's serum, the L. E.-cell phenomenon became clearly positive. Positive L. E. serum was heated at 56 C (132.8 F) for between 30 and 60 minutes. Fresh leukocytes washed in sodium chloride solution and fresh leukocyte nuclei washed in sodium chloride solution gave negative results with this inactivated serum concerning the L. E.-cell phenomenon; after addition of fresh human or guinea pig serum, a few rosettes and a few classic L. E. cells were found. The patient's condition deteriorated, and he died in cardiac failure. The diagnosis of systemic lupus erythematosus was confirmed by autopsy.

Free-acting complement plays an important role in the production of the L. E.-cell phenomenon. Inactivation of a positive L. E. serum by heating is possible, when it is used with washed leukocytes and washed leukocyte nuclei. After addition of human or guinea pig complement to this system, a weakly positive L. E.-cell phenomenon reappears. The L. E.-cell phenomenon can be negative, notwithstanding the presence in the serum of the specific L. E. factor and of complement, if complement-inhibiting substances are also present. In this case the L. E.-cell phenomenon can be demonstrated by the addition of fresh complement. The L. E.-cell phenomenon may perhaps be inhibited by lack of complement.

Metastasizing Carcinoid. L. Heilmeyer and R. Clotten. German M. Month. 3:338-340 (Nov.) 1958 (In English) [Stuttgart, Germany].

The authors report on a 56-year-old man with metastasizing carcinoid of the small intestine, whose case was peculiar with regard to its clinical aspects and metabolic behavior. The clinical course of the disease was more severely malignant than usual, with a greatly enlarged liver, the surface of which

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

showed numerous nodules varying from the size of a pea to that of an apple. There were bouts of high fever, and the erythrocyte sedimentation rate was considerably increased. Flushes occurred very frequently and were particularly severe. Oliguria and tachycardia were present in the absence of fever. In contrast to these findings, the intermittently normal excretion of hydroxyindolacetic acid and the increased excretion of tryptophan in the urine were surprising and difficult to interpret. Another substance which gave the same color reactions as hydroxyindolacetic acid also was observed; it might have been hydroxyindolacetaldehyde, another intermediate-stage decomposition product during the oxidation of 5-hydroxytryptamine to hydroxyindolacetic acid, or the gluconate of this acid. Other tryptophan derivatives were present in the electrophoretic pattern of the urine. A particularly severe flush was observed after 2 intravenous injections, each containing 50 mg. of 5-hydroxyindolacetic acid; the excretion of hydroxyindolacetic acid in the urine was simultaneously increased, and 38.3 and 35.1 mg. of the administered amounts was recovered from the urine within 24 hours. A severe flush also was observed after the intramuscular administration of 2.5 mg. of reserpine.

A possible explanation for the puzzling normal excretion of 5-hydroxyindolacetic acid and the increased tryptophan excretion is suggested as follows. A loss of the enzymes, which contribute to the oxidative transformation of 5-hydroxytryptamine into 5-hydroxyindolacetic acid, may result from the dedifferentiation of the carcinoid cells; 5-hydroxytryptamine may then accumulate in the cells, and finally a retransformation in tryptophan and hydroxytryptophan, respectively, may occur, which cannot be distinguished with the techniques used. Though not verified, this concept seems plausible. Another explanation would be that the clinical manifestations in this patient were not elicited by hydroxytryptamine but by another tryptophan derivative. Clinically the conclusion is inescapable that extensive carcinoid metastases may be associated with a normal excretion of hydroxyindolacetic acid in the urine. In such cases simultaneous determination of tryptophan excretion may be of diagnostic value.

Diagnostic Value of Needle Biopsy of the Liver. A. Lattanzi and U. Urbano. Omnia med. 36:185-209 (May-Aug.) 1958 (In Italian) [Pisa, Italy].

Specimens of the liver were obtained by needle biopsy from 53 hospitalized patients. Primary or secondary neoplastic disease was present in 17 patients, subacute or chronic hepatitis with progression toward sclerosis in 17, cirrhosis of the liver in 14, systemic blood disease in 2, and reticuloendotheliosis in 1. Needle biopsy of the liver was the main diagnostic procedure in 21 patients; it contributed to the formulation of the diagnosis in 25; it had insignificant diagnostic value in 5; and it gave an erroneous response in 2. Of the 14 patients with cirrhosis of the liver, needle biopsy of the liver established the diagnosis in 5 patients; it confirmed a previously established diagnosis by clinical means and laboratory findings in 8; and it gave disagreement with the clinical picture in 1 [It seems that the specimen of the last patient was obtained from the intact part of the liver.] Needle biopsy of the liver is particularly useful for an early diagnosis in cirrhosis of the liver.

Of the patients with subacute or chronic liver disease, needle biopsy of the liver was the main diagnostic means in 7 patients; it confirmed a previously established diagnosis in 7; and it was of insignificant diagnostic value in 2. Needle biopsy of the liver in subacute or chronic liver disease may also have a prognostic value; it can aid in detecting a latent sclerotic progression at a stage when the disease appears to be clinically cured. Of the 17 patients with primary or secondary neoplastic disease, needle biopsy of the liver was the main diagnostic means in 10 patients; it confirmed a previously established diagnosis in 4; it was of insignificant diagnostic value in 2; and it gave a discordant response with other procedures in 1. Needle biopsy of the liver in patients with neoplastic disease was supported and guided by the findings of laparotomy. The authors conclude that needle biopsy is an innocuous and fairly reliable diagnostic procedure for the establishment of the histological picture of various hepatic diseases and that it seems to be superior to other laboratory methods.

The Role of Hemodialysis (Artificial Kidney) in Acute Poisoning. G. E. Schreiner. A. M. A. Arch. Int. Med. 102:896-913 (Dec.) 1958 [Chicago].

The role of the artificial kidney in human poisoning may be considered from 2 points of view: the removal of (1) dialyzable poisons and (2) nephrotoxic poisons; the latter produce damage to the kidneys and are not different from other causes of acute renal insufficiency. In some instances, general toxicity may be produced from the poison itself, while in others it is a produce of the uremic syndrome. The effective use of hemodialysis is based on the following assumptions: 1. The poison molecule can diffuse through cellophane from plasma water and has a reasonable removal rate, or dialysance. 2. The poison is distributed in accessible body-fluid compartments. If substantial fractions of the absorbed poison dosage are bound to protein molecules, concentrated in important fluid compartments (e. g., cerebrospinal fluid), or attain a significant intracellular concentration, then effective dialysis will be sharply limited. This restriction is diminished, however, if the "loculated" portion is in diffusion or chemical equilibrium with a significant moiety in the plasma water. 3. There is a relationship between toxicity and the blood concentration and duration of the body's exposure to this circulating poison. 4. The amount of poison dialyzed constitutes a significant addition to the normal body mechanisms for dealing with the particular poison.

Many types of acute poisons are not susceptible to hemodialysis when measured against these considerations. Anticholinesterase compounds, as an extreme example, act much too rapidly for a favorable relationship between blood level and clinical toxicity. The same is probably true of the tissue necrosis due to the phosphorus content of rat-paste and matchstick poisoning.

The author is concerned with poisons for which removal by dialysis has been demonstrated by chemical measurement or reversal of clinical state. These include various barbiturates and salicylates, bromide, thiocyanate, ammonia, strontium, radiocalcium (Ca^{45}), tritium, and glutethimide. The author reviews the role of hemodialysis in the study and treatment of acute poisoning on the basis of 8 years' experience embracing 24 patients with dialyzable poisons and 15 patients with nephrotoxic injury. Survival rates were 83 and 47%. Barbiturate, salicylate, bromide, glutethimide (Doriden), and diphenylhydantoin (Dilantin) poisoning are reviewed in detail, with illustrative case histories appended. The first known instance of successful dialysis of severe methyl salicylate poisoning is presented, with reduction in blood salicylate level from 110 to 29 mg. per 100 cc. Early dialysis is suggested to abort the full clinical picture from dialyzable poisons and nephrotoxic injury.

Treatment of Chronic Asthma with Prednisolone: Significance of Eosinophils in the Sputum. H. M. Brown. Lancet 2:1245-1247 (Dec. 13) 1958 [London].

The subcommittee on clinical trials in asthma of the British Medical Research Council in 1956 had found no real advantage in cortisone acetate treatment of chronic asthma, compared with bronchodilator drugs. Analysis suggested that its methods were not beyond criticism; so general practitioners in the Derby area were asked to refer chronic asthmatic patients to the chest clinic to take part in another trial with prednisolone. This included patients who were already receiving steroid therapy, as well as those who joined the trial later. There were 90 patients in all. The trial was limited to patients who had had chronic bronchospasm for at least a year, and who had proved refractory to all other forms of treatment over at least one month. Early in the trial it was found that the distinction between asthma and chronic bronchitis with predominant bronchospasm was difficult.

The discovery of eosinophilic sputum in patients who responded dramatically to prednisolone prompted the improvisation of a method of examining the sputum and made it possible to separate the true asthmatics with eosinophilic sputum from the others. The success of this method suggested the examination of the sputum of patients receiving prednisolone. Corticosteroids clear the blood of eosinophils, but it was found that this did not happen in the sputum. Eosinophils in large numbers in the sputum were associated with a good response to prednisolone, and few or no eosinophils with a poor response.

Except when bronchospasm was very severe, the dose given was 5 mg. thrice daily for a week, followed by reassessment and adjustment of dose. All patients were given notes warning them of the dangers involved in prednisolone therapy. As a further safeguard, notes on the dangers of treatment were issued to family physicians. Each patient was told to take as little prednisolone as possible to keep him from wheezing. When wheezing had ceased for a few days, the dose was reduced by 2.5 mg. every 3 days until wheezing returned slightly. It should then be increased by 2.5 mg., so that wheezing disappeared again, and then continued at that level for about 10 days, when a further attempt should be made to reduce the dose. Thus, the patient was constantly trying to reduce the dose and finally stop treatment. Often patients were too enthusiastic in reducing dosage, so that spasm got out of hand and 15 mg. a day was needed for a week or so to control it. With these methods and by careful supervision and the use of antibiotics when needed, the risk of side-effects and complications was minimized. The screening technique for eosinophils in the sputum is described.

In some patients treatment with prednisolone had to be continued for a long time. Which is the lesser evil, disabling asthma or the dangers of long-term prednisolone treatment? All patients who had to make this choice chose to continue treatment. The elderly bronchitic patient with severe bronchospasm rarely benefited. Younger patients who obtained complete relief from bronchospasm usually had little or no residual dyspnea once the bronchospasm had disappeared. On the other hand, older asthmatics in whom emphysema had developed were still dyspneic. Experience showed that, if there was no improvement within 2 weeks on 15 or 20 mg. of prednisolone per day in the absence of purulent sputum, no significant benefit would be derived from continuing treatment. Prednisolone was used in children only when antispasmodics were of no avail, when there was emphysema and a poor prognosis, when the child had constant bronchospasm punctuated by exacerbations, and after eosinophils had been demonstrated in the sputum. Though prednisolone is effective in suitable cases, it never does more than suppress the asthmatic state, and it does not abolish eosinophils in the sputum, though the quantity is much reduced.

Value of Thyrotropin Stimulation Test in Diagnosis of Myxedema. T. Friis, L. K. Christensen and M. S. Andersen. Ugesk. laeger **120**:1545-1548 (Nov. 20) 1958 (In Danish) [Copenhagen].

Investigations confirm that thyrogenic myxedema in patients given thyroidin preparations can be excluded if the patients react to thyroid-stimulating hormone (TSH) with fairly normal absorption of radioiodine (I^{131}) in the thyroid gland. TSH tests with 4 U.S.P. units of TSH were carried out in 33 patients treated with thyroidin. Eleven had thyrogenic myxedema; they did not react to TSH with increased absorption of I^{131}. Of the 22 patients who presumably did not have myxedema at the start of treatment, 6 did not react to TSH; the thyroid gland is thought to have undergone atrophy in these cases as a result of thyroidin treatment.

Ammonia Intoxication Treated by Hemodialysis. J. E. Kiley, J. C. Pender, H. F. Welch and C. S. Welch. New England J. Med. **259**:1156-1161 (Dec. 11) 1958 [Boston].

Increased concentration of ammonia has been observed in many patients with hepatic coma. On the basis of investigations to determine whether ammonia present in the blood could be removed by a Kolff type of artificial kidney, the authors reported in 1955 that ammonia was removed by an artificial kidney with a dialysance varying from 50 to 80 ml. per minute when blood flow was 100 ml. per minute and membrane area was 12,000 sq. cm. They now report the application of hemodialysis to 5 patients who were comatose with ammonia intoxication. All these patients had advanced liver disease and lapsed into coma, with elevated blood ammonia levels, after massive gastrointestinal hemorrhage. All had ascites, and the prognosis was considered sufficiently poor to warrant trial of a new treatment. All were treated by esophageal tamponade, gastric lavage, and catharsis. A modified Kolff rotating-drum type of artificial kidney was used.

Three patients were treated by dialysis in the hope of relieving overwhelming ammonia intoxication of the exogenous type. No untoward effect of dialysis was observed. The first 2 patients came out of coma after the dialysis. Dialysis in the third patient was too limited by ordinary standards (only 11 liters of blood ran through the artificial kidney) to be of much therapeutic significance. This patient did not regain consciousness and died 2 days after the dialysis was terminated at a time when the first 2 patients were again alert and rational. In these 3 patients ammonia intoxication was not associated with any other biochemical disorder of comparable significance. In the other 2 patients severe ammonia intoxication was associated with other biochemical abnormalities. In each of these last 2 patients dialysis removed large amounts of ammonia nitrogen and other nonprotein-nitrogen constituents of the blood. In one of these 2 patients the temporary improvement noted was dramatic. Thus, 4 of 5 patients showed clinical improvement after effective dialysis. In the patient who died, dialysis was ineffective because of blood clotting. The authors conclude that ammonia may be removed by hemodialysis from patients suffering from ammonia intoxication, and that removal of ammonia by dialysis may be beneficial.

Microlithiasis of Pulmonary Alveoli. D. Hojman, R. B. Podio and O. C. Barreiro. Rev. Asoc. méd. argent. **72**:411-417 (Oct.) 1958 (In Spanish) [Buenos Aires].

Microlithiasis of the pulmonary alveoli is a rare familial and congenital disease of unknown origin. The disease consists of absorption of calcium salts by the lung parenchyma and the formation of microliths of various sizes, which occupy the pulmonary alveoli in innumerable quantities. The disease follows its course without symptoms or in presence of mild dyspnea for several years. It causes chronic cor pulmonale and insufficiency of the heart. It can be detected by chance during a routine roentgenologic examination of the chest. The roentgenograms of the chest are characteristic, showing complete bilateral opacification of the lungs, which involves the whole structure with the exception of the apex. The respiratory symptoms reported by the patients, as well as those heard on auscultation of the chest, are out of proportion to the extensive lesions of the lungs, as shown in the roentgenograms. Of the total 44 cases reported in the literature, an autopsy was performed in 12 cases, and a biopsy in 11. The pulmonary disease is restricted to the pulmonary parenchyma, the pulmonary alveoli, and the consequent pulmonary heart. All other organs and structures are normal. The microliths are free within the alveoli, the walls of which are normal and in rare cases involved by fibrosis. On touch, the lung gives the sensation of being a pumice stone. Blood vessels, bronchi, and pleura of the involved lungs are normal. If the lung tissue is put in water, it sinks. On cutting, it cracks like cutting metal. The cutting surface looks as if it were sandpaper.

A man, 58 years old, reported for consultation with symptoms of insufficiency of the heart. He had had moderate dyspnea for 18 or 20 years. Clinical examination showed a chronic pulmonary heart and very mild respiratory disorders detected on auscultation of the chest. The roentgenograms of the chest were typical of microlithiasis of the pulmonary alveoli. All other organs and structures were normal. It was learned that 2 brothers of the patient had died of the same disease and that his 5-year-old son apparently had the same disease in an early stage. Prior to death the patient was given a diagnosis of microlithiasis of the pulmonary alveoli. Partial autopsy with histological studies of tissues from the lower lobe of a lung confirmed the clinical diagnosis.

Mild and Severe Varieties of Erythema Multiforme Exudativum: Observation of Several Cases. G. Manganelli. Gior. clin. med. 39:1327-1353 (Sept.) 1958 (In Italian) [Bologna, Italy].

The author reports on 15 patients with erythema multiforme exudativum, 7 of whom had the mild variety, 4 the severe variety, and 4 the intermediate variety of the disease. In addition to the conventional symptoms, the patients with the mild variety developed high fever. The patients with the severe variety, also known as the Stevens-Johnson syndrome, manifested some, but not all, of the common features of this syndrome, which ran a fatal course in 2 patients. The intermediate variety was characterized by mild symptoms with involvement of the gastrointestinal tract in all 4 patients and an affection of the kidneys in 3. The renal lesions appeared during the resolutive phase of the disease and persisted for a certain period of time after diarrhea, vomiting, and cutaneous lesions had subsided.

The author concludes that in this series the mild and the severe varieties of erythema multiforme exudativum appeared to be facets of the same disease, because some of the symptoms which were not apparent in one were present in the other. Involvement of the viscera developed in both varities, and a higher erythrocyte sedimentation rate was observed in both. The Stevens-Johnson syndrome seemed to represent only one form of erythema multiforme exudativum. The clinical features of erythema multiforme exudativum in some of these patients were similar to those of the collagen diseases. Among these were a precarious state of health, arthralgic pain, and cutaneous erythema.

The Incidence of Peptic Ulceration in Some African Tribal Groups. A. B. Raper. Tr. Roy. Soc. Trop. Med. & Hyg. 52:535-546 (Nov.) 1958 [London].

The incidence of gastric and duodenal ulcer in 3 groups of people of diverse origins, living in the neighborhood of Kampala, Uganda, was assessed by means of a consecutive series of postmortem examinations. For male subjects, the gross incidence of peptic ulcer in the local people was 13.68%, in Nilotic immigrants 5.4%, and in immigrants from the southwest (especially Ruanda) 20.6%. The generally high incidence, 15.3% in men and 4.65% in women, is in contradiction of previous reports from tropical Africa. It is suggested that the causes of peptic ulcer are abundantly operative in tropical Africa but that the conditions in which the disease may be brought to notice are rarely fulfilled.

The results of this survey give confirmation to the view that peptic ulcer is commoner in immigrants from the southwest than in the people of central Uganda, but it was an unexpected finding that another group of immigrants, the Nilotics, should show a lower incidence than the local people. The author feels that it is not necessary to postulate variations in "racial" susceptibility to ulcer, at least as the immediate cause, for in the population from which these data are drawn the 3 groups are exposed to very different conditions of life. The immigrants from the southwest represent the section of the community subject to the greatest stress; their life is the hardest, their food the poorest, often long intervals elapse between their meals, the prevalence of disease is greatest among them, and fears for the future must be constantly present in their minds. These considerations offer an entirely adequate explanation for any proneness to ulcer that they may exhibit. They certainly offer a marked contrast to the Nilotic immigrants, in whom the lower incidence of ulcer could well be related to the fact that these people are better fed and have a more carefree attitude toward life, a consequence partly of their greater efficiency as wage earners. The local people occupy in these respects a position intermediate between the 2 immigrant groups. Thus, if any influence is to be attached to innate susceptibility to ulcer, it depends in these 3 groups on the success with which they face the complexities of life, and thereby encourage or impede the action of the well-recognized etiological agents of peptic ulcer.

Intestinal Polyposis and Mucocutaneous Pigmentation (Peutz-Jeghers Syndrome): Further Comments and Report of an Additional Case. L. C. Bartholomew and D. C. Dahlin. Minnesota Med. 41:848-852 (Dec.) 1958 [St. Paul].

The authors point out that an earlier report from the Mayo Clinic on intestinal polyposis and mucocutaneous pigmentation (Peutz-Jeghers syndrome) described 6 new cases and reviewed 69 cases reported in the literature to the end of 1955. Since then a sufficient number of additional cases have been presented to justify further reflections on this disease, particularly on the potentially malignant character of the polyps. The authors present the history of an 82-year-old man, who in addition to urinary retention had experienced a severe substernal pain, and in whom an electrocardiogram showed the typical findings of an acute anteroseptal myocardial infarction. The patient died 6 hours later. Postmortem examination revealed coronary sclerosis, a recent infarct in the apex and anterior wall of the left ventricle with rupture of the myocardium into the pericardium, benign prostatic hypertrophy, and bilateral hydronephrosis. An incidental finding was that of single polyp, 1 cm. in diameter, in the fundus of the stomach and 6 polyps in the colon. The examiner's awareness of the aspects of the Peutz-Jeghers syndrome led to a search for, and the demonstration of, the characteristic pigment on the mucosa of the lips. Microscopically, all the polyps were benign.

In the 2 years that have elapsed since the earlier review of 75 cases, 42 additional cases of this syndrome came to the authors' attention, bringing the total to 117. The pigment was present on the lips in 115 of the 117 patients, thus making this the single most important physical sign. It was noted on the buccal mucosa in 103 of the 117 patients. The polyps were present in some part of the small intestine in 108 of the 117 patients. The exceptions included 7 patients with polyps in the rectum alone, 1 with polyps in the colon and stomach, and 1 with polyps in the rectum, colon, and stomach. Episodes of abdominal pain and some form of gastrointestinal bleeding were the major symptoms. Recurrent attacks of colicky abdominal pain occurred in 99 of the 117 patients. About 55% of the patients have some evidence of the familial nature of this disease.

The major aspect of this syndrome that remains debatable pertains to the potential malignant nature of the polyps. The peculiar histological characteristics of the polyps that the authors were able to study led to the suggestion that these tissue excrescences represent a developmental abnomality rather than true adenomatous polyps. The 3 predominant types of cells of the normal mucosa of the small intestine, namely, columnar absorbing cells, goblet cells, and coarsely granular Paneth cells, were found within the jejunal and ileal polyps that were studied in 5 patients. The authors feel that the over-all pattern of these polyps strongly suggests that they are the result of a growth disturbance similar to that which produces hamartomas of the lungs. None of the polyps which they studied in the Peutz-Jeghers syndrome appeared malignant or even premalignant. However, although the colonic and rectal polyps studied in patients with the Peutz-Jeghers syndrome have appeared benign, there is no evidence to suggest that these patients are immune to the development of ordinary adenomatous polyps and carcinomas in these locations.

Intolerance for Gluten in a Patient with Regional Ileitis. J. R. Chan Jon Chu. Nederl. tijdschr. geneesk. 102:2150-2154 (Nov. 1) 1958 (In Dutch) [Amsterdam].

The author presents the history of a 26-year-old woman who for nearly a year had been troubled with abdominal pains and constipation. After a more severe attack of pain accompanied by vomiting, diarrhea developed, which persisted. There were 3 or 4 loose or watery stools daily. Loss of weight resulted. "Chronic appendicitis" and later tuberculous peritonitis were suggested. Diarrhea and weight loss continued despite conservative treatment. Regional ileitis was diagnosed at laparotomy, and an ileocecal resection was performed. Twenty months later, at a second operation for regional ileitis, the lower third of the remaining small intestine was resected. Abdominal pains, diarrhea, and loss of weight recurred after both operations, and after the second operation the diarrhea gradually became more severe, and symptoms of malabsorption developed. Fat balance studies revealed extreme steatorrhea. The patient was treated with a gluten-free diet; prompt improvement followed, and the fat absorption rose. The gluten-free diet combined with up to 25 mg. of prednisone daily effected no increase in fat absorption. Treatment with gluten-free diet alone resulted in complete clinical recovery.

Angiographic, Functional and Clinical Aspects of Obliterating Arteriopathy of the Lower Extremity and Their Relationship. V. Uberti and G. Japichino. Omnia med. 36:130-183 (May-Aug.) 1958 (In Italian) [Pisa, Italy].

The authors investigated the correlation between morphologic, functional, and clinical aspects of occlusion at various sites of an affected artery in 487 patients with arterial occlusion of the lower extremity. Obstruction of the superficial femoral artery was present in 112 patients (22.4%); it was related to atherosclerosis in 106 patients and to thromboangiosis in 6. Peripheral blood flow was in most instances fairly adequate in relation to the collateral circulation. Intermittent claudication developed in 104 instances, pain at rest in 17, cyanosis in 14, and ulcer in 4. Occlusion of the popliteal artery was present in 19 patients (3.8%); it was related to atherosclerosis in 11 patients and to thromboangiosis in 8. Digital plethysmography revealed that peripheral blood flow was more pronounced in patients with occlusion of the popliteal artery than in those with occlusion of the superficial femoral artery. Clinical symptoms were also more marked; intermittent claudication affected all patients; trophic lesions and pain at rest were also more intense.

Occlusion of the femoral-popliteal tract developed in 23 patients. The occlusion was severe, and plethysmograms showed considerable reduction in peripheral blood flow. Severe clinical symptoms were directly related to the reduced peripheral blood flow. Occlusion of the anterior tibial artery was present in 21 patients. Plethysmograms showed variations from extreme reduction to almost normal pattern in peripheral blood flow. Many instances of severe ischemia were observed: pain at rest in 12 patients, hypothermia in 10, and cyanosis in 12. Occlusion of the posterior tibial artery was present in 27 patients. Total occlusion was more frequent than partial occlusion. Plethysmographic patterns showed a considerable decrease in peripheral blood flow at rest and a marked increase after reflex vasodilation. Multiple occlusions of the arteries of the leg, which were mostly related to thromboangiosis, were observed in 116 patients (23.2%). Plethysmograms showed a considerable decrease in peripheral blood flow. The main clinical feature was a rapid development of ischemia. Associated occlusions of the arteries of the thigh and the leg were present in 67 patients. Reduction in peripheral blood flow was considerable and was often very high. Intermittent claudication, pain at rest, and necrotic lesions were frequent and severe.

The clinical symptoms related to arterial occlusion in patients of this series were often worse than those usually observed at corresponding sites of obliterated arteries of the lower extremity. The succession of clinical symptoms reflected the gradual development and the extent of arterial lesions.

Kahler's Disease and Proteinuria. J. Warter, P. Métais and J.-M. Mantz. Semaine hôp. Paris 34:2919-2930 (Dec. 4) 1958 (In French) [Paris].

The authors studied the incidence of proteinuria in 16 patients with multiple myeloma (Kahler's disease). Renal manifestations generally appeared simultaneously with pathological changes in the bones, but in one patient the occurrence of anuria led to the diagnosis of multiple myeloma. Proteinuria was manifested in one patient several months and in another patient 4 years before other symptoms and signs of multiple myeloma appeared. The filter-paper electrophoresis of urine from patients with proteinuria revealed more often a mobility of gamma globulins, and more rarely of beta globulins, with or without a corresponding serum globulin peak. Thus, in 3 of the 16 patients globulinuria was the initial symptom and the premonitory sign revealing multiple myeloma. The diagnostic value and prognostic significance of electrophoretic analysis of urine are emphasized, particularly in patients with severe proteinuria of unknown origin.

The various physicochemical aspects of Bence Jones proteins are considered, such as their thermal solubility, their electrophoretic pattern, and their amino acid composition. The problems regarding the origin of Bence Jones proteins, their release into the circulation, and their rapid excretion through the kidneys due to their low molecular weight (about 44.000) are discussed. Nitrogen metabolism was studied in patients with multiple myeloma by evaluating the intestinal absorption of methionine and of glycine labeled with radio carbon (C^{14}). The intensity of protein synthesis, which characterizes myeloma, entails an indubitable state of nitrogen deficiency. The hyperabsorption of the amino acid administered in such cases seems to be a manifestation of this deficiency.

The Clinical Significance of Diverticulosis. R. S. Boles Jr. and S. M. Jordan. Gastroenterology 35:579-582 (Dec.) 1958 [Baltimore].

The authors report on 134 men and 160 women with diverticulosis, who were studied at the Lahey Clinic in Boston. The average age of the patients was 55 years. One hundred nineteen patients (40%) had a history of definite laxative abuse, and 33 patients (11%) complained chiefly of diarrhea. The medical management of the patients with diverticulosis was the same as that of those with irritable colon, namely, a regimen of diet, medication, and hygiene designed to combat spasm, since it has long been the opinion of one of the authors that spasm at the mouth of the diverticulum causes retention of material within the diverticulum with resultant inflammation and infection. During the average follow-up period of 15 years with an undetermined and undoubtedly varying degree of fidelity to the prescribed treatment, complications were noted in 119 of the 294 patients, with the following distribution: diverticulitis in 73 patients (24.8%); hemorrhage in 16 (5.4%); obstruction in 15 (5.1%); and perforation or fistula in 15 (5.1%). Of the 73 patients with diverticulitis, 28 (38%) had superimposed complications, and of the 221 patients with only diverticulosis, 18 (8.1%) had complications without evidence or history of clinical diverticulitis; thus, nearly 5 times as many patients with active diverticulitis had superimposed complications as did those with diverticulosis. Forty patients, i.e., more than half of the 73 with diverticulitis, had only one attack of this complication. Multiple attacks of diverticulitis in the other 33 patients were associated with more than twice as many complications (57.5%) as were single attacks (22.5%). Cancer occurred in 16 (5.4%) of the total group of 294 patients with diverticulosis, with no increase of incidence in areas of diverticulosis or diverticulitis.

These findings have special significance at this time when surgical advances have produced much greater safety in the single-stage resection for diverticulitis and a resultant enthusiasm among many surgeons for earlier radical treatment of this disease. According to the authors, diverticulitis should still be regarded as a medical disease until complications make surgical treatment necessary.

Old and New Tests for Bilirubin in the Urine. J. M. Bleyer and F. Steigmann. Am. J. Digest. Dis. 3:947-952 (Dec.) 1958 [New York].

The investigations described here were undertaken to compare the efficiency and usefulness of 2 older (Rosenbach and Smith) and 2 newer (Franklin and Ictotest) tests for the detection of bile in the urine. Two hundred forty-seven freshly voided morning urine specimens of 129 patients with icteric scleras and clinical and biochemical (liver profile) signs of liver disease were examined for bile and albumin; simultaneously blood was drawn for the determination of the serum bilirubin (van den Bergh). Each urine sample was tested for albumin with 20% sulfosalicylic acid and for bile with each of the following tests: 1. Rosenbach's modification of the Gmelin test: The urine is filtered through a small filter paper. One drop of yellow nitric acid is introduced into the cone of the paper. The appearance of any colored ring indicates positivity. 2. Smith's test: The urine is overlayed with tincture of iodine, diluted with 9 times its volume of alcohol. An emerald green ring at the zone of contact shows the presence of bile pigments. 3. Franklin's bilirubin test: Ten drops of urine are dropped on a tablet made of plaster of paris and containing barium chloride. Two drops of Fouchet's reagent (one-half strength) are added to the surface of the tablets. The presence of bilirubin in the urine is denoted by the appearance of a color ranging from slight bluish-green to deep green. 4. Ictotest: Five drops of urine are placed on an asbestos–cellulose test mat. An Ictotest reagent tablet, containing *p*-nitrobenzenediazonium–*p*-toluenesulfonate, sulfosalicylic acid, sodium bicarbonate, and boric acid, is placed in the center of the moistened area. Two drops of water are dropped on the tablet, allowing the water to run down the sides of the tablet. If the test is positive, the mat around the tablet turns purple.

In addition, 46 urine specimens of 23 control patients with no signs of jaundice and/or liver disease, who had albumin, blood, sugar, or ketone bodies in their urine or had been on different medications, were tested by Ictotest alone to investigate the effect of various urine contents on the Ictotest reaction. Ictotest was found to be the most sensitive. The simple and economical Rosenbach test came close to the sensitivity of Ictotest. The height of the indirect serum bilirubin and the amount of bile in the urine were not always parallel.

SURGERY

Palliative Treatment of Obstructing Processes in the Esophagus and Cardia with Intubation. E. Skielboe. Ugesk. laeger 120:1222-1225 (Sept. 11) 1958 (In Danish) [Copenhagen].

In cancer of the esophagus and cardia, where the possibility of radical operation is excluded and marked difficulty in swallowing even liquid food is not lessened by roentgen-ray treatment, intubation according to Souttar's method seems to be the most satisfactory treatment, except in tumors in the pars superior of the esophagus. In cases in which the tumor is soft or is longer than Souttar's tube, Mousseau-Barbin's plastic tube is useful and requires no special equipment for application. Palliative intubation was carried out in 51 patients with obstructing and mainly malignant processes in the esophagus and cardia—in 41 according to Souttar and in 10 with the Mousseau-Barbin plastic tube. The average time of survival was only 4 or 5 months, but palliative intervention was justified. Souttar's method should be applied generally in preference to gastrostomy, and in suitable cases it is admirably supplemented by Mousseau-Barbin's plastic tube.

Treatment and Prophylaxis of Acute Cardiovascular Insufficiency During Mitral Commissurotomy. S. I. Smelovsky, T. M. Barbinyan and Y. M. Panova. Khirurgiya 34:21-26 (no. 8) 1958 (In Russian) [Moscow].

Acute cardiovascular insufficiency requiring intra-arterial blood transfusion occurred in 46 patients, of a total number of 135, during a mitral commissurotomy performed for stenosis of the left mitral valve. In patients with this complication hypoxia was successfully treated by intra-arterial blood transfusion. Acute cardiovascular insufficiency is caused by the operation itself and by hemorrhage from the left auricular appendage. The weakness of the left ventricle adapted for minimal blood filling also plays a certain role. After dilatation of the mitral orifice this weakness of the left ventricle may give rise to acute insufficiency. Prophylactic intra-arterial blood transfusion is recommended for the prevention of acute cardiovascular insufficiency. Employment of this method, with the administration of epinephrine, during a commissurotomy prevents acute cardiovascular insufficiency. The authors consider that the best site for transfusion is the arteria tibialis posterior. At times the intra-arterial blood transfusion causes pain in the course of the main blood vessels of the lower extremity and paresis of the peroneal nerve. Development of acute cardiovascular insufficiency in 40% of cases of mitral commissurotomy justifies the employment of prophylactic intra-arterial blood transfusion in all cases of surgical treatment of stenosis of the mitral valve.

Mediastinal Chemodectoma. T. J. Madden. Ann. Surg. 148:943-950 (Dec.) 1958 [Philadelphia].

The author reports on a 28-year-old pregnant woman with a mediastinal tumor of aortic body origin which was detected in a routine chest roentgenogram taken in the 6th month of pregnancy. Bronchoscopic examination showed downward displacement of the right upper lobe bronchus. A right-sided thoracotomy was performed, and the entire tumor was removed with a short segment of the innominate artery. Three months later the patient was delivered of a normal female infant. Nineteen months after removal of the tumor the patient was alive and apparently free of disease. Microscopic examination of the operative specimen revealed an extremely vascular tumor, consisting of polyhedral cells with finely granular eosinophilic cytoplasm. The cells were arranged in groups separated by thin fibrous septums. Throughout the tumor there were small clumps of iron-containing, golden-brown pigment. Ten additional cases of carotid-body tumors arising in the mediastinum and in relation to the base of the heart and great vessels were collected from the literature and summarized, together with available recent follow-up data on patients who were living at the time of the original reports.

This summation of experience with mediastinal chemodectomas, together with the known facts about the related and more common tumors of carotid bodies and jugular glomera, is the basis for the following tentative conclusions about the natural history of the tumors. Mediastinal chemodectomas are slow-growing tumors which rarely metastasize but may recur locally after incomplete excision. They occur anywhere in the mediastinum, not necessarily in the usual sites of normal aortic glomera. They may be associated with tumors of similar type in other locations. Surgical treatment may be difficult, and a conservative approach seems to be warranted. Treatment by x-ray is not likely to be effective.

A Report Upon a Patient Five Years Following Resection of the Abdominal Aorta for Recurrent Carcinoma. S. W. Moore. Surg. Gynec. & Obst. 107:709-711 (Dec.) 1958 [Chicago].

The patient was a woman who was 56 years old when she was admitted to the New York Hospital in May, 1952, because of a mass in her abdomen. On Jan. 11, 1949, in another hospital, she had been subjected to an anterior resection of the sigmoid colon for adenocarcinoma with perforation. The abdominal mass detected 3½ years later was firm, fixed, rounded, and 10 cm. in diameter, and lay in the left lower quadrant. At operation on May 21, 1952, a large tumor, 10 by 6 by 4 cm., was found lying between the aorta and the sigmoid colon. Although not fixed, the tumor was adherent to the aorta and to the left common iliac artery. The left ureter entered the mass. There were no metastases in the liver or lymph nodes along the aorta. The tumor was thought to be a local recurrence of the sigmoid carcinoma resected 3½ years previously. To remove the mass, it was necessary to resect en bloc the aorta, both common iliac arteries, and the left ureter together with the tumor. A homograft of abdominal aorta with bifurcation was inserted in the defect by end-to-end anastomosis.

Immediately after operation, there was excellent bilateral pulsation in the femoral and dorsalis pedis arteries. The gross specimens, as well as microscopic sections, showed recurrent carcinoma invading, but not yet penetrating, the lumen of the aorta. Twenty-five days later, on June 16, 1952, the sigmoid colon and left kidney were removed. Four months later, on Nov. 17, a cholecystectomy for chronic cholecystitis with cholelithiasis was carried out without incident. On Oct. 20, 1954, 2 years later, a bilateral subtotal thyroid lobectomy was performed for nontoxic nodular goiter. Now 5½ years have elapsed since resection of the secondary carcinoma, and this patient is quite well save for minor complaints. There is no evidence of cancer, and no loss of weight. Both femoral and dorsalis pedis vessels on both sides are readily palpable with good pulsations.

Prescalene Node Biopsy. K. Cruze, R. F. Hoffman, W. B. Hayden and F. X. Byron. Ann. Surg. 148:895-898 (Dec.) 1958 [Philadelphia].

The authors report on 151 patients, between the ages of 23 and 81 years, on whom 164 prescalene lymph node biopsies were performed with the aid of local anesthesia in the section of thoracic surgery of the Veterans Administration Center in Los Angeles between January, 1953, and October, 1957. A conclusive tissue diagnosis was rendered in 51 (31.1%) of the 164 biopsies. This procedure may prevent needless operation. The indications should include suspected bronchogenic carcinoma or abnormal pulmonary shadows. Bilateral biopsy is indicated in some instances. Prescalene lymph node biopsy yielded positive results in 26 (38.2%) of 68 cases of bronchogenic carcinoma proved by autopsy, clinical, or other ancillary methods. A compilation of the results of prescalene lymph node biopsies reported by other workers and collected from the literature revealed about 30% positive biopsies for all lesions. Complications did not occur when the biopsy was performed with the patient under local anesthesia.

Portacaval Anastomosis: A Study of 12 Pre- and Post-operative Cases. L. Leger and R. Roy-Camille. Presse méd. 66:1673-1676 (Oct. 29) 1958 (In French) [Paris].

Twelve patients with cirrhosis, who had undergone portacaval anastomosis, were followed up for a period of 6 to 18 months after operation. Portal hypertension returned to normal values in 3 patients, it was decreasing over several months in 8 patients, in 2 of whom it began to increase after a while; and it remained unchanged in 1 patient who died of hemorrhage a year after the operation. Another patient died in hepatic coma 21 months after the operation. Clinical improvement, potency of the anastomosis, and cessation of hemorrhage were observed in this series of patients after the surgical treatment. Disappearance of the blood reflux followed the operation, but it returned in a slight degree in 3 patients. Roentgenologic examination of esophageal varices in 7 patients after the operation showed that they remained unchanged in 1 patient and diminished in 6. Liver function improved in 1 patient, remained unchanged in 2, and deteriorated in 4.

Contributions to Surgical Treatment of Portal Hypertension. M. A. Khelimsky. Khirurgiya 34:10-14 (no. 8) 1958 (In Russian) [Moscow].

Splenectomy with simultaneous omentohepatofixation and omentorenopexis was employed by the author in patients with the syndrome of portal hypertension and with thrombophlebitic splenomegaly and splenogenic cirrhosis of the liver. He operated on 11 patients who were admitted to the clinic because of hemorrhages due to varicose veins of the esophagus. There were 6 men, 4 women, and a 13-year-old girl. After the operation a normal blood picture was reestablished in all the patients, and thrombopenia, ascites, and hemorrhages disappeared. Ten patients have resumed their work. One patient in whom omentohepatofixation alone was performed without omentorenopexis died 1½ years after the operation as a result of thrombosis of a branch of the superior mesenteric artery.

Emergency Surgery for Severe Upper Gastrointestinal Hemorrhage: An Analysis of Sixty-Four Cases. W. E. Switzer and W. W. Nichol. A. M. A. Arch. Surg. 77:843-850 (Dec.) 1958 [Chicago].

This report is concerned with patients who were operated on as emergencies because of severe upper gastrointestinal bleeding. The case series was accumulated during the years from 1950 through 1957 at a large Army hospital and includes active-duty military personnel and their dependents, retired military personnel, and Veterans Administration beneficiaries. Not included are the many patients whose bleeding ceased with conservative treatment or those persons who were operated on electively after a bleeding episode. During the period mentioned, 353 patients entered the hospital with upper gastrointestinal bleeding. Sixty-four (18.1%) were operated on. All but 2 of these 64 patients were men. The ages of the patients ranged from 17 to 74 years; 33 were under, and 31 were over, 50 years of age. There was an increase in the number of patients requiring surgery for gastrointestinal bleeding in the fall. The month of November alone accounted for 12 (18.8%) of the entire group, in contrast to July when no operations were done for gastrointestinal bleeding during the entire 8-year period. Both hematemesis and melena occurred in 44 patients, melena only in 13, and hematemesis only in 7.

After commenting on preoperative hemoglobin and hematocrit values, on transfusion requirements, preoperative endoscopy, and roentgenoscopy, the authors state that 56 of the 64 patients were treated by subtotal gastric resection, and 2 by total resection. The remaining 6 patients were treated by one of the following: ligation of the bleeding gastric ulcer; suture of a stomal ulcer; exploration and pyloroplasty; suture and packing of ulcer; exploration only; and suture of laceration at the gastric cardia associated with repeated vomiting (Mallory-Weiss syndrome). The following points are emphasized: 1. These patients benefited from a combined medical-surgical evaluation of their problem. 2. The results of the early diagnostic procedures of endoscopy and upper gastrointestinal x-rays appeared to justify the effort required, without undue risk to the patients. 3. Blood transfusion requirements in these patients should be thought of in terms of one-half to several times the patient's estimated normal blood volume. 4. Although the mortality rate in the above-50 age group was more than triple that of the below-50 age group, it was also true that the lives of 24 of the 31 patients above 50 years were prolonged by surgical intervention. 5. Recurrent bleeding and sepsis were the complications most frequently associated with death.

Favorable Postgastrectomy Results in Billroth II Patients with a Small Stoma. J. J. McCaughan Jr. and R. F. Bowers. A. M. A. Arch. Surg. 77:837-842 (Dec.) 1958 [Chicago].

The Billroth 2 type of gastric resection has been widely accepted, because it has the lowest peptic ulcer recurrence rate of any of the procedures in use, while the mortality and immediate morbidity rates are comparable. However, the late postgastrectomy findings of weight loss, diarrhea, and the dumping syndrome with accompanying weakness are believed to be more frequent than with other procedures, notably gastroenterostomy and the Billroth 1 procedure. The postoperative study of patients who have undergone the Billroth 2 type of gastric resection suggests that the symptoms are due to loss of the pyloric sphincter and stomach, which is usually associated with rapid emptying of the stomach. This sudden flow of food and fluid into the jejunum must be slowed down. To test the validity of this concept, the authors deliberately formed a small stoma in the Billroth 2 operation. The purpose of the small stoma was to retard the gastric emptying. Roughly, 1.5 to 2.5 cm. has been the selected size of the small stoma, although this cannot be accurately measured. A stoma of 2.5 to 6 cm., or larger, is regarded as large by the authors. They found some large stomas of the Pólya type to be from 4 to 6 cm. in diameter. The measurement of the stomas is not accurate, but is estimated by the surgeon with finger and thumb.

The authors compared the results obtained by Billroth 2 gastrectomy in 100 patients with small stomas with those in 100 with large stomas. Follow-up studies by personal interview revealed that the postgastrectomy syndrome was reduced approximately by one-half in the small-stoma group as compared with the control group. Weight loss was reduced from an average of 9.83 lb. in the control group to 3.84 lb. in the small-stoma group. Weakness, which seemed to be the commonest and severest complaint of the control group, was decidedly better in the small-stoma group. Diarrhea was approximately equal in frequency in the two groups. Subtle distinction in postcibal symptomatology in the two groups did not seem feasible in this series. If there was doubt about the presence of postgastrectomy symptoms, the authors used the oral glucose intake test (250 cc. of 50% glucose by mouth), which proved to be very practical and produced the symptoms if the patient had really experienced the postgastrectomy syndrome. It was often difficult to separate psychosomatic symptoms from the actual ones, but the glucose test was helpful in these instances. A small number of patients experienced the dumping syndrome even when stomal obstruction was present.

Making the partially obstructing stoma proved difficult. At the end of the operation, the surgeon often could not predict the degree of stomal obstruction that would follow. The best results were obtained from stomas that would just admit one small finger.

Gastric Polyps. K. Kettunen. Ann. chir. et gynaec. Fenniae 47:300-312 (no. 4) 1958 (In English) [Helsinki].

Of 14,566 patients who underwent roentgenologic examinations in the department of roentgenology of the Maria Hospital in Helsinki between 1948 and 1955, gastric polyps were detected in 37. The author reports on these 37 patients (15 men and 22 women), whose ages ranged from 32 to 88 years, with an average age of 60.2 years. Epigastric distress and pain were the most prominent and significant complaints. Achlorhydria was found in 19 of 21 patients tested. Four patients had pernicious anemia. Malignant transformation was present in 3. Thirteen of the 37 patients had single gastric polyps, 4 had 2 polyps, and 20 had 3 or more. Generalized polyposis was present in 3 patients.

Treatment in 26 of the 37 patients was conservative, while partial gastric resection was performed on 7, exploratory operation on 1, simple excision on 2, and subtotal gastric resection on 1. It is suggested that roentgenologic examinations, with the aid of barium as contrast medium, be used in establishing a diagnosis of gastric polyps; gastroscopic examination should be used as a supplement to the roentgenographic study, since it may reveal polyps overlooked by the latter method and vice versa. If malignant disease cannot be determined on the basis of gastroscopic or roentgenologic examination, an exploratory operation is recommended.

Excisional Treatment of Aneurysm of Celiac Artery. H. B. Shumacker Jr. and H. Siderys. Ann. Surg. 148:885-889 (Dec.) 1958 [Philadelphia].

Of 35 patients with aneurysm of the celiac artery, whose cases have been reported in the literature, 31 died of rupture. None of the patients was treated successfully by surgery. This fact prompted the authors to present the case of a patient with multiple arteriosclerotic abdominal aneurysms, who has recently been treated successfully by surgery. The patient was a 41-year-old woman who was admitted to the department of surgery of the Indiana University Medical Center in Indianapolis in August, 1957. Aneurysms of the celiac axis, the splenic artery, and both common iliac arteries were excised. Ischemia of the stomach and liver followed temporary occlusion of the celiac artery and was obviated after resection of the celiac aneurysm by anastomosis of the remaining stump of the celiac artery and the main hepatic artery. Aortic-iliac continuity was restored by insertion of a bifurcation graft. The patient had an uneventful convalescence and was discharged on the 12th postoperative day. In view of the extent of her arteriosclerotic disease and the high normal level of her serum cholesterol, she was placed on a low-cholesterol and low-fat diet. When she was seen 3 months later, she was well and had been working full time. The liver edge was not palpable, and the peripheral pulses were excellent.

Congenital Pyloric Stenosis Treated by the Ramstedt Operation: A Review of 1,018 Cases. S. Feggetter. J. Internat. Coll. Surgeons 30:696-700 (Dec.) 1958 [Chicago].

The author reports on 1,018 children with congenital pyloric stenosis, who underwent the Ramstedt operation in Newcastle, England, between 1940 and 1956. Seventeen children died, representing a mortality rate of 1.6%. The operative and postoperative complications are listed, and a typical case in a 4-week-old boy is described. Medical accounts refer occasionally to congenital pyloric stenosis from the year 1700 onward, but the first accurate description of the disease was presented by Hirschsprung in 1887. All the signs and symptoms result from obstruction due to a pyloric tumor, which is caused by true hypertrophy of the circular muscle of the pyloric canal. The development of the tumor depends on the presence of a recessive gene; it is to be expected, therefore, that the incidence of the anomaly will increase. It now occurs in approximately 3 of each 1,000 live births. In 1946, the over-all mortality rate in England and

Wales was 20%. The differential diagnosis includes infectious vomiting, pylorospasm, and the intestinal atresias. The treatment of choice is the Ramstedt operation performed with the aid of open ether anesthesia. It has been observed that, when children in a given area have been treated by one or two surgeons interested in this type of work, with the assistance of a pediatric team and a skilled anesthetist, the results of the Ramstedt operation have been substantially improved.

Surgical Treatment of Disease of the Prostate in Patients with Diabetes Mellitus. H. Eufinger and D. Borm. Beitr. klin. Chir. 197:11-15 (no. 1) 1958 (In German) [Munich].

The authors report on 12 men, between 56 and 81 years, with disease of the prostate and diabetes mellitus who were operated on at the surgical clinic of the University of Kiel, Germany, between 1947 and 1956. Of the 12 patients, 9 had adenoma of the prostate, and 3 had carcinoma of the prostate. Ten patients underwent electroresection, and 2 were subjected to suprapubic prostatectomy according to Freyer. Four of the 10 patients required a second resection, and, therefore, 16 operations were performed on the 12 patients. The blood sugar values of the patients varied between 122 and 257 mg. per 100 cc., and the amounts of sugar excreted in the urine varied between 0.59 and 14.7 Gm. The diabetes mellitus was discovered in 3 patients only after admission to the surgical clinic, and its duration in 4 patients varied between 17 and 23 years. Six patients were hospitalized because of acute retention of urine, with 300 to 2,000 cc. of fluid contents of the bladder, and the other 6 were hospitalized because of dysuria and pollakiuria. One of the patients died on the third postoperative day of pulmonary embolism. The remaining 11 patients were discharged from the hospital, and 10 were followed up after their discharge. One died 8 days later at home, one who had carcinoma of the prostate died 4 years after the operation, and one died 2 years after the operation. The remaining 7 patients are still alive and free of complaints of micturition. Four patients no longer require treatment with insulin. In 3 of these, the disease of the prostate caused a latent diabetes mellitus in patients of advanced age to become manifest, but the diabetes became latent again after surgical treatment of the prostate. Three patients are still receiving insulin, but the diabetic disturbance of metabolism is controlled by the drug.

These findings show that diabetes mellitus does not represent a contraindication to surgical intervention in patients with disease of the prostate. It seems that the type of the surgical procedure and the preoperative and postoperative administration of antibiotics and chemotherapeutic preparations, respectively, are of far less importance in the surgical treatment of diabetic patients with disease of the prostate than the preoperative control of the diabetic metabolism by the internist.

Importance of Early Operation in Congenital Atresia of the Extrahepatic Bile Ducts: Report of 10 Proved Cases. G. E. Schnug. Ann. Surg. 148:931-936 (Dec.) 1958 [Philadelphia].

The author reports on 10 newborn infants with obstructive jaundice caused by congenital atresia of the extrahepatic bile ducts. Five of these had atresia of the extrahepatic bile ducts which was surgically correctable. Two of the 5 were operated on, one successfully, at the age of 2 months, and the other unsuccessfully at the age of 6 months; the other 3 patients were not operated on, but autopsy revealed that the anomalies had been correctable. Marked liver changes secondary to atresia of the bile ducts were observed on autopsy. Even the one infant who was operated on successfully had advanced cirrhosis of the liver. She survived several hemorrhages and reached the age of 3 years, at which time it was felt that her vessels were large enough so that a splenorenal shunt could be made. Splenectomy also was done, and the patient is now a normal 5½-year-old girl. Her liver function has gradually improved over a period of years. In the 291 patients with congenital atresia of the extrahepatic bile ducts, whose cases were collected from the literature, the cause of death was most frequently failure of the liver. The atresia was surgically correctable in 68, and only 24 of these were reported as cured. It was also noted that almost all successfully treated patients were operated on when they were less than 2 months old.

Available diagnostic measures are inadequate in differentiating the various types of obstructive jaundice in the newborn infant. The reported data show that irreversible changes in the liver do occur early in patients with biliary atresia. Exploration within the first months of age has been recommended. Anastomosis between the extrahepatic biliary tree and the duodenum is the simplest and probably the procedure of choice. It seems quite definite that the liver damage and the complications and sequelae resulting from the damage are the cause of the poor results in the treatment of patients with correctable biliary atresia.

Antibiotic Therapy: Adverse Effects in Acute Appendicitis Before Diagnosis. R. B. Dietrick, C. W. Byrd and J. A. Lawson. Ann. Surg. 148:985-990 (Dec.) 1958 [Philadelphia].

Of 46 patients with acute appendicitis who were admitted to the surgical service of the Veterans Administration Hospital in Richmond, Va., between 1955 and 1957, 5 (10.9%) had been treated with antibiotics or sulfonamides before a diagnosis was established or before an operation was performed.

The authors believe that this therapy obscured the symptoms of appendicitis and thereby delayed and made the diagnosis more difficult. As a result of being unable to reach an early diagnosis, the morbidity, length of hospital stay, and expense of hospitalization were greatly increased. The experience with these patients indicates that appendicitis treated with antibiotics may lead to 2 different clinical pictures: (*a*) patients who are obviously ill, who have masked and atypical symptoms, and who require exploration on the basis of the clinical picture and (*b*) patients whose symptoms are so completely masked that no specific diagnosis can be made, who do not appear to require exploration on the basis of their clinical findings, and who settle into a state of chronic disability which may extend over many months, with occasional exacerbations.

The 5 patients treated with antibiotics had a large number of complications, either directly or indirectly, due to their primary disease. In one patient a severe wound infection developed, and he also required a skin graft to an ulcer caused by extravasation of arterenol, which was given to correct persistent severe hypotension postoperatively; an abscess arose in his McBurney scar 18 months after operation. Intestinal obstruction was caused in another patient by a volvulus about the point of adherence of the inflamed appendix to the terminal ileum. In a third patient persistent rectal stenosis occurred at the site of adherence of the appendix to the rectum. In still another patient gross hematuria was caused by genitourinary manipulations, and intestinal obstruction due to a great number of postoperative adhesions, resulting from chronic inflammation over a period of many months, required reoperation. Patients with undiagnosed abdominal pain should not receive antibiotics until appendicitis can definitely be excluded as a diagnosis. In patients admitted with abdominal pain in whom the symptoms are atypical, the examining physician should have a high index of suspicion that the patient may have received antibiotic therapy and should closely question the patient concerning this possibility. When the patient gives such a history, early exploration is indicated despite the paucity of physical findings.

Differential Diagnosis of Mitral Pathology. B. V. Petrovski and V. V. Zaretski. Vestnik khir. 81:28-33 (Nov.) 1958 (In Russian) [Leningrad].

Electrokymography (study of pulsations of various segments of the peripheral contour of the heart) has been successfully applied in the diagnosis of heart anomalies, 128 commissurotomies having confirmed its findings. The left atrium electrokymogram reveals best of all the peculiarities of mitral defects. The left atrioventricular valve stenosis is reflected by an inhibited and prolonged systole of the left atrium, the electrokymogram showing a diastolic plateau. After the atrial systole is over, a mitral valve insufficiency is disclosed by a regurgitation reflux indentation on the electrokymogram of the left atrium during the systole of the left ventricle. The existence of mixed mitral defects is evidenced on the electrokymogram by elements of left venous orifice stenosis and mitral valve insufficiency, the more advanced anomaly being revealed by the prevalence of its characteristics.

Clinical and Functional Assessment of Surgical Treatment of Mitral Stenosis: A Follow-Up. A. L. Izbinski and T. G. Blestkina. Vestnik khir. 81:33-40 (Nov.) 1958 (In Russian) [Leningrad].

Treatment of 110 patients by mitral commissurotomy is evaluated in a follow-up ranging from 6 months to 4 years. A favorable outcome was found in 86% of the cases. An adjuvant classification of third-degree competence of the "second barrier," devised by Izbinski and his co-workers, was added to the usual classification of blood circulation impairment in the preoperative and the postoperative assessment of the patient's condition. By "second barrier" the authors refer to the complex of pathological changes in the pulmonary parenchyma and in the pulmonary circulation developing on the basis of mitral stenosis. The unfavorable results were found to depend on (1) a failure of the commissurotomy itself, (2) a rather late recrudescence of rheumatic infection, (3) marked dystrophic myocardial changes, (4) intercurrent diseases, and (5) clear-cut symptoms of the "second barrier" complex before the operation. This adjuvant classification gives a more reliable appraisal of the patient's condition before surgery and has an important significance for the prognosis of late results. A fourth-degree circulatory impairment does not preclude surgical treatment of mitral stenosis, because an effective commissurotomy is often followed by a marked improvement in the patient's condition and even by a partial return to work fitness.

Indications and Contraindications for Shunt Operations in Portal Hypertension. S. Brandstaetter. Harefuah 55:242-243 (Nov. 16) 1958 (In Hebrew with English Summary) [Tel-Aviv, Israel].

According to Brandstaetter, a brief survey of the newer techniques indicates that splenoportography and measurement of the splenic pressure are the best methods available for determining whether portal hypertension is the cause of esophageal varices in a given case and whether portal hypertension is due to intrahepatic or extrahepatic block. In a patient with bleeding varices and portal hypertension, intrahepatic block is a clear indication for a shunt operation. Laboratory tests suggested by Linton proved to be a relatively reliable index in the selection of patients for portacaval shunt. A patient with repeated hemorrhages and borderline liver function tests is a bad risk for splenorenal shunt, and portacaval shunt is contraindicated. Uncontrollable ascites remains a contraindication to shunt procedures until more reliable statistical material has been gathered. As even in good-risk patients the operative mortality is still about 10%, the advisability of prophylactic shunt in patients with cirrhosis and varices who have never bled is still a moot problem.

The Use of Controlled Hypothermia for the Prevention of Ischemic Renal Damage Produced by Cross-Clamping of the Thoracic Aorta: Experimental Observations. R. Benvenuto and M. Serratto. Minerva med. 49:3948-3952 (Oct. 20) 1958 (In Italian) [Turin, Italy].

A study on hypothermia induced to protect the kidney against ischemic damage due to occlusion of the thoracic aorta is reported. The experiment was carried out on 18 male and female dogs, each having a body weight of 15 to 20 kg., divided into 2 groups. The first group was composed of 12 animals, 6 used as controls and operated on at a normal temperature and 6 operated on under hypothermia; a series of biopsies of the kidney was carried out in these animals after the operation. The second group was composed of 6 animals, 2 used as controls and operated on at a normal temperature and 4 operated on under hypothermia. Anesthesia was induced in all dogs with intravenous injections of Nembutal, 30 mg. per kilogram of body weight, and respiration was controlled by means of tracheal intubation and of a mechanical respirator. In the dogs subjected to hypothermia, the temperature was reduced to 32 C (89.6 F) by means of thermal blankets at the moment that the thorax was being opened, and to 28 C (82.4 F) when occlusion of the aorta by cross-clamping took place. Normal temperature, 37 C (98.6 F), was restored by introducing hot water in the thermal blankets. Occlusion of the aorta for one hour caused necrosis of the convoluted tubules of the kidney in all the animals used as controls. Biopsy performed soon after the restoration of normal temperature, and 24 and 36 hours after the operation, revealed no necrosis of kidney tissues in the animals operated on under hypothermia.

Necrosis of the proximal tubule, already on the way to recovery, was noticed in one animal on which biopsy was performed one week after the intervention. This animal also presented signs of spontaneous nephritis. Kidney function was seriously impaired in all the control dogs soon after the operation; it improved later, but it never returned to the condition it was before operation. In the dogs operated on under hypothermia, kidney function was slightly but temporarily impaired. Normal values were obtained in clearances carried out 1 or 5 weeks after the operation.

Rheumatoid Tenosynovitis: Diagnosis and Treatment. T. A. Potter and J. G. Kuhns. J. Bone & Joint Surg. 40A:1230-1235 (Dec.) 1958 [Boston].

The authors report on 154 patients with rheumatoid tenosynovitis who were treated at the Robert Breck Brigham Hospital in Boston and were followed for periods exceeding one year. Of these, 65 with only small swellings were treated conservatively with heat and support. Thirty of these have been cured, i. e., the tenosynovitis has disappeared and has not recurred. In 10, the lesion has become smaller but is still present; the remaining 25 did not respond to this method of treatment. Thirty-five patients with circumscribed lesions not larger than 1 in. in diameter were treated by injection of hydrocortisone, repeated at 2-week intervals; 15 of these showed complete disappearance of the swelling, the condition of 5 was improved, and 15 were therapeutic failures. In 30 patients with masses on the tendons larger than 1 in., the lesions were excised; 20 patients were relieved completely and had no recurrence, 3 had a slight recurrence of the swelling, and 7 had an early recurrence of the lesion. Tendon repairs, including resuturing, grafting, and transferring of tendons, were performed on 24 patients; in 10 of these the operation restored good function, improvement in function was observed in 2, and 12 were therapeutic failures.

Rheumatoid tenosynovitis is a common complication of rheumatoid arthritis; its slow, nonpainful development often results in failure of recognition and diagnosis. This lesion is found most commonly on the dorsum of the wrist, involving the extensor tendons. Diagnosis can be established only by microscopic examination of the diseased tissue. It can be suspected when swelling appears in and upon the tendons in the presence of rheumatoid arthritis. Treatment in the early stage should include heat, support, and relaxation of the tendon. It may be supplemented by injections of hydrocortisone into the mass every 2 weeks. When the swelling becomes large, excision of the diseased tissue as completely as possible is advised. Rupture of tendons requires surgical repair. No relationship could be established between rheumatoid tenosynovitis and Quervain's disease and snapping finger.

The Value of Shunt Operations for Portal Hypertension. D. Erlik. Harefuah 55:233-238 (Nov. 16) 1958 (In Hebrew with English Summary) [Tel-Aviv, Israel].

Of 17 shunt operations for portal hypertension, 10 were splenorenal shunts and 7 were portacaval shunts. Two of these shunt operations performed for Budd-Chiari syndrome were not analyzed. Shunting was performed for cirrhosis of the liver in 13 patients, and for extrahepatic block in the remaining 2. Of 6 patients on whom portacaval shunt was performed, 2 died within 10 days of the operation, but in these the liver function tests indicated that death was caused by hepatic insufficiency leading to coma. The other 4 patients are in satisfactory condition from 1 to 3 years after the operation; the severe preoperative hemorrhages did not recur. No deaths attributable to the operation occurred in 9 patients undergoing splenorenal shunts, but 3 of these patients died because of recurrent esophageal bleeding 2 weeks, 6 months, and 2 years, respectively, after the operation. The shunt was found to be thrombosed in all fatal cases. The progress of the other 6 patients was satisfactory with no recurrence of bleeding.

On the basis of these observations and of literature reports, the author concludes that shunt operations are serious procedures owing to the dangers of immediate and delayed complications. The decision to perform a shunt operation requires thorough study of the individual patient, but there should be no wavering if operation is required. In case of severe hemorrhage from esophageal varices, a shunt should be performed before another bout of bleeding may be fatal.

The choice of shunt is a source of controversy. The portacaval shunt is the best as regards function and, therefore, the most reliable in preventing hemorrhage, but for this type liver function tests must at least be fair. When the liver tests are seriously impaired, the splenorenal shunt is preferable, although it is prone to closure by thrombosis. This type of shunt gives excellent results in extrahepatic block. Shunt operations should not be performed to prevent anticipated hemorrhage. The only exceptions are cases in which splenectomy is performed for congestive splenomegaly with severe hypersplenic phenomena. In these cases the splenic vein should be saved from thrombosis by performing a "prophylactic" splenorenal shunt. When severe and repeated hemorrhages from esophageal varices occur at short intervals, a Blakemore tube should be introduced into the esophagus to stop the bleeding. Then a suitable shunt is constructed with the balloon still in place. One or 2 days after the operation the balloon can be removed without danger of further bleeding.

Antibiotics for Colon Surgery. I. Cohn Jr. Gastroenterology 35:583-591 (Dec.) 1958 [Baltimore].

Evaluation by standardized methods of 28 agents for intestinal antisepsis permitted their division into recommended and less satisfactory groups. All the groups recommended for general use in intestinal antisepsis are combinations of neomycin with another poorly absorbed agent. A clinical trial of a triphasic antibiotic administration program was undertaken in patients who were subjected to surgical intervention on the colon; these patients were selected from the Louisiana State University surgical service at Charity Hospital of Louisiana and from 4 other hospitals in New Orleans. The 3 phases of the program were as follows: (1) preoperative preparation with a combination of 1 Gm. of neomycin and 200 mg. of tetracycline (Achromycin) given every hour for 4 hours, then every 6 hours for a total of 72 hours; (2) intracolonic instillation of a powder containing 250 mg. of tetracycline and 1.25 Gm. of neomycin into the lumen of the colon whenever the colon was opened for any reason; and (3) postoperative intraluminal injection of a mixture of 150 mg. of tetracycline and 750 mg. of neomycin, dissolved in 10 cc. of sterile saline solution; this mixture was injected 3 times daily for the first 5 postoperative days through a plastic tube, which was inserted into the colon proximal to the point of anastomosis of colotomy and exteriorized through a stab wound.

Between July 1, 1955, and Dec. 31, 1957, 200 patients were evaluated on this antibiotic program for colon surgery. No cases of pseudomembranous enterocolitis were observed, and the absence of fistulas and of peritonitis in the 67 patients who received postoperative treatment through the plastic tube encouraged further study of this form of therapy. Complications were not completely eliminated in these surgical patients, though, and it should not be expected that any amount of antibiotic therapy would eliminate all complications, nor should such therapy replace sound surgical principles. Clinical experience with these 200 patients over 2½ years has substantiated the experimental evidence that a high concentration of antibiotics should be maintained within the lumen of the intestine before, at the time of, and after surgical intervention on the colon.

Arthrogryposis Multiplex Congenita. N. G. Mead, W. C. Lithgow and H. J. Sweeney. J. Bone & Joint Surg. 40A:1285-1309 (Dec.) 1958 [Boston].

During a period of 31 years, 68 patients with arthrogryposis multiplex congenita were treated at the Shriners' Hospital for Crippled Children in Chicago. The authors report on 40 of these, who were examined and treated and on whom close follow-up studies were carried out. Twelve patients were followed from infancy into adulthood. All 4 extremities were involved in 20 patients, both lower extremities in 11, both lower and one upper extremity in 7, both upper extremities in 1, and one lower and one upper extremity in 1. The causation and pathology of arthrogryposis are not well understood, and there is no general agreement concerning them. Until the true nature of this congenital disorder, which is characterized by multiple rigid joint deformities, is known, there is little advantage in using other terms for the condition. The occurrence of the disease in one member of each of 4 sets of identical twins, 2 of which are in this series, seems to exclude hereditary factors as the cause and to cast doubt on theories of intrauterine mechanical, circulatory, or toxic causes. The negative family histories further tend to exclude the theory that heredity is a cause.

The primary pathological site may be either in the spinal cord or in the muscles. It is believed that the fibrosis around the joints and in the subcutaneous tissues is a part of the pathological process and not merely secondary to intrauterine inactivity. Mental deficiency is infrequent in patients with arthrogryposis. When present, it does not appear to be more than coincidental. Only 2 of the 40 patients were considered to be below normal in intelligence; one of these had cerebral palsy also, and it was felt that the mental deficiency was related to this condition. The joint deformities are difficult to correct and to maintain in correction. Function may be poor because of stiffness or lack of muscle power even when the deformity has been overcome. Stiff joints must be placed in the position of function, and unstable limbs must be braced for weight bearing. If these things are accomplished, results will be satisfactory. Patients with arthrogryposis, even though severely handicapped, generally make a satisfactory adjustment and live successful lives. Severe pain is not often present despite the poor mechanics many of these people must endure.

Congenital Pseudarthrosis of the Tibia. H. B. Boyd and F. P. Sage. J. Bone & Joint Surg. 40A:1245-1270 (Dec.) 1958 [Boston].

The authors report on 9 girls and 6 boys with congenital pseudarthrosis, who were operated on at the Campbell Clinic-Hospital in Memphis, Tenn. Of the 15 patients, 7 who were treated between 1941 and 1948 have reached skeletal maturity, and end-results are reported not only regarding treatment but also regarding social and economic status. The remaining 8 were operated on after 1948, and since none of these have reached skeletal maturity, they cannot be included in an end-result study. All 7 patients in the first group had repeated reconstructive operations: 1 of these was a surgical failure because treatment resulted in below-the-knee amputation; 3 had moderate results, 2 of them requiring braces and 1 requiring a shoe elevation; 3 were operated on successfully, having no longer complaints referable to the lower extremities. From a social and economic point of view treatment was successful in 6 of the 7 patients. The one surgical failure was a social and economic success.

There are two distinct types of congenital pseudarthrosis of the tibia. In the first, a cystic defect, with or without fracture, is present, and the pathological findings resemble those in fibrous dysplasia. The second shows sclerosis and tapering of the bone ends, probably due to a constricting band of fibrous tissue. In this type, union is more difficult to secure. The causative factors are still undetermined, but congenital pseudarthrosis is probably due to a maldevelopment of the mesodermal structure during the 5th week of fetal life, with an associated abnormality occurring in the nerve pathways to the affected leg. Early surgical treatment before the development of marked deformity is advised. In the first type, the cyst should be curetted and the defect filled with bone chips; additional bone grafting may or may not be necessary. In the second type, a wide resection of the constricting band of pathological soft tissue should be done, combined with suitable bone grafting and adequate internal and external fixation; the latter, achieved by casts followed by suitable braces, should be continued until skeletal maturity or until a tibia of relatively normal size develops. In patients with extreme deformity, amputation may be indicated when one is reasonably sure that a prosthesis will provide a better weight-bearing extremity than the best extremity that could be obtained after successful reconstructive surgery. In making the decision, the surgeon should compare the function of an artificial leg with the best result that can reasonably be expected after reconstructive surgery, not with a normal extremity. Repeated clinical and roentgenologic examinations should be continued until skeletal maturity is reached. If at any time evidence of narrowing of the bone or sclerosis of the medullary cavity appears, prophylactic operative intervention with wide resection of the constricting band of scar tissue should be done. In addition, reinforcing grafts should be placed about the area of previous pseudarthrosis. Multiple operations may be necessary during the growth period. A registry for congenital pseudarthrosis of the tibia is needed in order to enhance knowledge of the causation, pathology, treatment, and end-results through the age of skeletal maturity.

Significance of Mineral Metabolism in Surgery. E. Carstensen. Chirurg 29:536-541 (Dec.) 1958 (In German) [Berlin].

The author studied the metabolism of water and minerals in 80 patients who underwent operations of moderate or extensive type at the surgical clinic of the University of Hamburg–Eppendorf, Germany; these included such surgical interventions as gastrectomy, cholecystectomy, amputation of the rectum, pulmonary resection, strumectomy, and radical removal of mammary glands. The studies of metabolism were carried out preoperatively and postoperatively. In the course of and after the surgical intervention, the patients were given infusions of dextrose and fructose without the addition of minerals. Rarely the amount of transfused citrated blood exceeded 250 to 500 cc. The variations in electrolytes in the serum and the urine were markedly uniform, independently of the extensiveness of the surgical intervention, provided that no complications occurred in the field of the operation. After increased elimination of potassium on the first and the second postoperative day, the potassium reached its lowest value in the serum on the 3rd or the 4th postoperative day. On the 6th or the 7th postoperative day, the serum potassium level and the potassium elimination became normal again. It seems likely that the increased postoperative potassium elimination by the kidneys and the resultant relative hypopotassemia may be a sequela of the stimulation of the adrenal cortex by the "operative stress." Postoperative determination of the cortisone serum level revealed that it was considerably increased and that the highest value was reached 6 hours after the operation. On the 5th postoperative day the cortisone serum level was restored to normal. The postoperative hypopotassemia seldom reached values of less than 4 mEq. in the serum. The term "compensated hypopotassemia" is suggested because of the absence of clinical symptoms and since the condition does not require any therapeutic measures.

Decompensation of the electrolyte and particularly of the potassium metabolism threatens only after postoperative complications, such as peritonitis, ileus, major suppuration, and intestinal fistulas. Prolonged postoperative feeling of thirst for more than 2 or 3 days, or increasing thirst, is suggestive of the onset of such complications. Increased loss of potassium may be manifested by feeling of weakness, hypotonia of the skeletal muscles, cyanosis of pulmonary origin, atonia of smooth muscles, nausea, and vomiting. The organism then is no longer able to compensate spontaneously for the potassium loss, and administration of infusion solutions containing electrolytes and carbohydrates becomes indispensable. The electrolyte losses of patients with an uneventful postoperative course are clinically insignificant, and electrolyte substitution therapy is not necessary. An exaggerated infusion activity may even be more harmful than useful. Therapeutic electrolyte infusions with flame-photometric control are required in patients with postoperative complications occurring in the operative field.

Potassium Metabolism and Potassium Substitution Therapy in Patients Subjected to Surgical Interventions. G. M. Dummer. Chirurg 29:541-544 (Dec.) 1958 (In German) [Berlin].

In the course of surgical intervention and in the postoperative phase, potassium exerts a particular influence on the biological behavior, i. e., on the composition and distribution of electrolyte solutions in the 3 body spaces of the patient, namely, the cell, the interstice, and the intravascular space. Every normal operative intervention is associated with a loss of potassium. Intracellular acidosis with alkalosis of the extracellular fluid results from a change in hydrogen ions. In the absence of postoperative complications the organism is able to compensate for the alkalosis of the extracellular fluid, but the acidosis in the cells may be compensated for only when the organism has taken up again adequate amounts of potassium and monosaccharides and a normal glycogenesis has been reestablished.

The symptoms of potassium deficiency, i. e., a serum potassium level of less than 13 mg. per 100 cc. (3.3 mEq. per liter), may vary from general weakness to flaccid paralysis of the extremities with abolition of tendon reflexes; they have often prevented an operation from being successful. The request, therefore, is advanced to provide for potassium substitution before, in the course of, and after the surgical intervention. Substitution by mouth represents the most favorable method. Fruits, vegetables, meat, milk, and their derivatives are rich in potassium, but it is difficult to compute a diet with an excess in potassium while commercial potassium salts can be added easily to the diet. Oral administration of potassium, however, is rarely feasible in surgical patients, and, therefore, infusion treatment is the method of choice.

Two groups of surgical patients must be distinguished as follows. The first group consists of those without significant preoperative or postoperative potassium loss, and the second group consists of those with a preoperative potassium deficiency or those in whom a major postoperative loss of potassium is caused by the necessary removal of gastric juice and intestinal juice respectively. The solution used for patients in the first group should contain 2 Gm. of potassium chloride per liter, corresponding to about 1 Gm. of potassium. It should also contain sodium chloride. Up to 1,500 cc. of such a solution was used by the author with highly satisfactory results on the day of the operation, and amounts of 500 to 1,000 cc. were given on the following days according to need. The pH value of 7.2 of this solution corresponded with the blood pH. The addition to the solution of 25 Gm. of dextrose and 25 Gm. of fructose accelerated the transport of potassium into the cell body. In patients with severe hypopotassemia, an adequate amount of sterile 10% potassium chloride solution and dextrose was added to the infusion solution. The use of a flame photometer for serum potassium and sodium determinations is strongly advocated.

NEUROLOGY & PSYCHIATRY

Leucotomy for Pain. A. Elithorn, E. Glithero and E. Slater. J. Neurol. Neurosurg. & Psychiat. 21:249-261 (Nov.) 1958 [London].

The authors report on 13 men and 12 women, between the ages of 31 and 78 years, who underwent operations of leukotomy type for the relief of intractable pain and were followed up for periods ranging from 17 to 78 months, with an average of 40 months. Nine patients had "extensive" operations, consisting of full bilateral "standard" operation in 7 and full unilateral operation with partial incision on the contralateral side in 2. Three patients had only a unilateral standard leukotomy, and 13 patients had "limited" operations in which half or less of the white matter of the frontal lobes was divided. The results of the operations were assessed by the patient and by the relative most concerned, clinically; they also were assessed with a rating scale, including symptoms, employment, family relationships, and community relationships, thus still depending on the subjective evaluation of quantitative data but, nevertheless, permitting a more detailed assessment of the efficacy of the treatment.

Clinical evaluation suggested that 17 of the 25 patients had been clearly helped by the operation. Twenty (80%) showed an over-all gain on the social rating. However, only 8 (35%) of 23 patients and 8 (38%) of 21 relatives thought that the operation had been worthwhile. The tendency for patients and relatives to be dissatisfied with a leukotomy for intractable pain was related to the observation that, although most patients admitted to some improvement in their symptoms, only 5 thought that their pains were less intense. With regard to the type of operation performed, the patients and relatives all agreed and the clinical assessment showed that more favorable results were obtained from "extensive" operations than from "limited" ones. In contrast, patients who had "limited" operations tended to show bigger gains on the social rating scale. This discrepancy is related to the fact that, while more, extensive operations tend to produce greater relief from suffering, they also are more likely to lead to socially crippling defects of personality.

The results obtained support the following conclusions. Operations on the frontal lobes—unless they are very extensive—do not impair the patient's ability to perceive and react appropriately to a painful stimulus, but they produce relief by impairing his ability to elaborate a persisting attitude or mood. The probability that leukotomy will provide relief for a patient with intractable pain depends, first, on the severity of the painful sensations and, secondly, on the nature of the psychological reaction. In patients in whom the pain is not severe and the psychological reaction is largely a depressive or anxious preoccupation with symptoms, the prospects of some degree of relief are high. If pain is severe and frequent, little permanent relief is to be expected. In patients with hysterical tendencies, these may be increased, but, since the anxiety which provokes the hysterical symptoms may be reduced, the total change is often a gain in social adaptation. Operations on the frontal lobe are an unsatisfactory treatment for intractable pain, but, if pain cannot be alleviated by other means, then in carefully selected patients operations of leukotomy type may produce both relief from suffering and an improved social adjustment.

A Controlled Study of the Effects of Leucotomy. A. A. Robin. J. Neurol. Neurosurg. & Psychiat. 21:262-269 (Nov.) 1958 [London].

The author compared the results in 155 women and 43 men treated by leukotomy at Runwell Hospital in Wickford, Essex, England, with those in 198 control patients matched for chronicity (length of stay in hospital), age on admission, sex, and being treated at the same time. Leukotomy did not appear to (1) improve the chances of discharge from the hospital, (2) accelerate discharge, (3) reduce the chances of readmission, (4) delay readmission, (5) reduce the number of readmissions, (6) reduce the total period of readmission, (7) improve hospital behavior as judged by ward level, and (8) significantly increase the death rate. A second leukotomy did not significantly improve the patients' prospects of discharge in relation to the controls. The sex of the patients did not influence the results of leukotomy. "Recovered" patients, i. e., patients who have been discharged from hospital and have not since been readmitted to Runwell or any other mental hospital in England and Wales under the same name, had at least the same level of adjustment in the control group as in the group subjected to leukotomy, and they seemed similar in that they showed the same distribution of diagnoses, ages, and lengths of stay in hospital. No evidence was found for a delayed operative response after leukotomy.

GYNECOLOGY & OBSTETRICS

The Transmission of Transfused Sickle-Trait Cells from Mother to Fetus. N. T. Macris, L. M. Hellman and R. J. Watson. Am. J. Obst. & Gynec. 76:1214-1218 (Dec.) 1958 [St. Louis].

This paper describes a method by which it is ascertained whether intact maternal erythrocytes cross the placental barrier. Donor blood with the sickle-cell trait but without sickle-cell anemia was selected for this purpose. When erythrocytes with the sickle trait are exposed to a decreased oxygen tension, they assume a characteristic sickled configuration which is easily recognized. A group of pregnant women was, therefore, injected with sickle-trait blood, and the blood of their infants was examined for sickle cells. The subjects of this study were 25 Rh-positive pregnant women at or near term. Specimens of their blood were examined for sickle cells, and in all except one none were found. When available, the husband's blood was also examined for sickling. The selection of subjects in this study was governed largely by the blood group of the sickle-trait donor blood that was available. They ranged in age from 17 to 38 years and included 18 Negroes, 4 Puerto Ricans, and 3 whites.

Twenty-one of the subjects were transfused with 500 ml. each of sickle-trait whole blood. In 3 instances the supernatant plasma in 500 ml. of whole blood was removed, allowing the sickle-trait cells to be given in a reduced volume. The elapsed time, between the end of transfusion and delivery, ranged from 40 minutes to 153 hours and 2 minutes. Nineteen of the women were delivered vaginally, and 6 by cesarean section. Whole blood was collected both from the umbilical cord at delivery and from the mother within 12 hours after delivery. Sickle-cell preparations of the mother's and infant's bloods were prepared.

Sickle cells were found in the umbilical cord blood of the newborn infant in 3 of the 25 cases studied. The placenta in each of the 3 cases was normal on gross inspection. The placental passage of sickle-trait cells in 3 of 25 experimental subjects adds to the already existing evidence that in a small percentage of patients maternal red blood cells traverse the placental barrier and are found in appreciable numbers in the fetal circulation. The mechanism of transfer is obscure. While breaks are known to occur in the fetal circulation, the pressure relationships are thought to be such that direct passage must always occur from fetus to mother. Direct transfer of maternal cells against the pressure gradient is not feasible. Furthermore, the venous pressure cannot fall below the amniotic fluid pressure, which is the same as the intervillous space pressure. The only remaining possibility is active transfer by the process of planocytosis, which has been shown to occur for particulate matter. When certain rough assumptions were made from the data, the fetus in at least one instance must have received at least 5 ml. of sickle-trait cells. Should the placenta be unable to distinguish between sickle-trait and normal maternal cells, the transfusion to accomplish this must have been a bit more than 40 ml., which is altogether unlikely. One is left with the assumption that the microvilli distinguish between natural and unnatural maternal cells, engulfing only the latter. The facts of transfer can no longer be denied. The mechanism remains a baffling mystery.

The Nasal Mucus Smear in Toxemias of Pregnancy. E. H. Abou-Shabanah, J. G. Boutselis, W. J. Frajola and J. C. Ullery. Am. J. Obst. & Gynec. 76:1248-1263 (Dec.) 1958 [St. Louis].

Observations indicate that among pregnant women who are apparently normal during early pregnancy there are some who are potentially preeclamptic, and that significantly greater weight gain occurs in the patient with preeclampsia between the 13th and 20th weeks of pregnancy than in the normal or hypertensive pregnant patient. Eclampsia has been known to occur sometimes without the development of proteinuria or hypertension. Although edema is one of the principal signs of the preeclamptic state, it is possible for true preeclampsia to occur with no pitting edema and with only excessive weight gain. This weight gain is usually too rapid to be accounted for by the growth of the fetus or the gravid uterus. Perhaps an intracellular accumulation of fluid occurs in preeclampsia. Healthy pregnant women also have delayed water excretion and some sodium chloride retention, presumably because of increased activity of the adrenal cortical hormones. In the past storage of water and sodium chloride without obvious edema was difficult to understand. Today, with evidence in favor of the ability of sodium to replace intracellular potassium, the latter being excreted, occult edema can be explained. In other words, one expects sometime during the course of preeclampsia–eclampsia to find a change in the ratio between sodium and potassium excreted in body fluids. The study of potassium excretion in the urine revealed no characteristic curve for preeclampsia. In this paper the authors demonstrate the value of the nasal mucous smear in the study of the toxemias of pregnancy.

In a preliminary study, nasal mucous smears were made on 5 patients at the Demerdash Hospital, Cairo University, Egypt—3 in the preeclamptic phase and 2 in eclamptic convulsions. The excretion of sodium and potassium in the nasal and cervical mucus of normal pregnant women was studied in an attempt to relate the sodium and potassium excretion to the fern phenomenon. Some of the mucus, as obtained, was spread on a slide for the fern test, while the remainder was treated with a minimum of dilute hydrochloric acid and water, filtered to remove strands, and the filtrate analyzed for sodium and potassium content by flame spectrophotometry. The nasal mucus from 30 pregnant women, who on admission presented signs and symptoms of late toxemia of pregnancy, was examined. Nasal smears were taken on admission, then hourly in severe cases, and twice daily in others.

Nasal mucous smears were classified on the basis of the presence or absence of arborizations. When arborizations were present, a further classification was made according to whether the pattern showed beaded arborizations (unlinked arborizing crystals) or an atypical fern (deficient or incomplete fern arborization). Oils of different refractive indexes were used to identify the presence of calcium or potassium on the smear. The absence of arborization (negative fern phenomenon) in a smear of nasal mucus is associated with preeclampsia-eclampsia. The sodium-potassium ratio of the nasal mucus of normal pregnant women and of pregnant women with hypertension and/or renovascular disease is greater than 1, whereas in preeclampsia-eclampsia it is reversed. The use of index of refraction oils on smears of nasal mucus will enable the physician to detect preeclampsia by a simple office test. This test also guides him in the management of, and the prognosis for, both mother and fetus.

Management of the Pregnant Diabetic. W. S. Jones. Diabetes 7:439-445 (Nov.-Dec.) 1958 [New York].

Among the 140,665 deliveries at the Providence (R. I.) Lying-in-Hospital in the 31-year period from 1927 to 1957, there were 273 pregnancies in 169 diabetic women. After excluding abortions and dubious diagnoses, there remained 251 viable pregnancies, on which this study is based. The prevalence of prepaid insurance coverage has created a progressive shift from clinic to private patient status. The 93 private deliveries were conducted by 26 different obstetricians, and 43 internists and general practitioners participated in their medical management. This lack of uniformity of control is in marked contrast to that in a teaching hospital. Furthermore, many patients resist long periods of hospitalization desirable in the last trimester, and the community obstetric service is obliged to accept emergency cases and miscellaneous drifters, infrequently seen in specialized centers. This has a devastating effect on fetal loss statistics.

Answers were sought to two questions: What kind of diabetic women lose their babies, and under what circumstances? Fetal loss was investigated in relation to the age of the mother, the age at which she acquired diabetes, and the duration and severity of her diabetes. The great majority of fetal deaths was associated with 3 clinically detectable physiological complications: 1. In the presence of acidosis, the fetal loss was 51%. 2. In women with preeclampsia, 32% of the infants died. 3. In cases in which hydramnios was recorded, the wastage was 37%.

The author feels that progress in improving fetal salvage in diabetes seems painfully slow. The loss over a 31-year span was 28%, and it has remained close to 25% in recent periods. Much of this loss occurs among older women and among those with mild forms of diabetes—patients in whom better results should be achieved. Much of the fetal loss stems from small but costly slips in diabetic control and from debatable obstetric judgment. The author believes that improved fetal salvage will come about, not by emptying the uterus earlier or by doing more cesarean operations, but by paying closer attention to the control of diabetes and toxemia.

Diverticulitis, Sigmoiditis and Perisigmoiditis from Gynecologic Viewpoint. J. A. Abolins. Nord. med. 60:1568-1569 (Oct. 30) 1958 (in Swedish) [Stockholm].

Diverticulitis can cause both diagnostic and therapeutic difficulties. The disease seems to occur more frequently. When a resistance in the small pelvis is found, especially with inflammation, the possibility of diverticulitis, sigmoiditis, or perisigmoiditis should be considered. The history gives valuable information. Usually for a long time before the first consultation there has been constipation, diarrhea, and flatulence. The commonest symptom is abdominal pain on the left side, together with fever. Roentgenologic examination is desirable, but in the acute stage it is not without danger. Often the first roentgenologic examination does not give certain diagnosis. Conservative treatment is advised. The 6 cases of diverticulitis described were observed during a half-year period in patients admitted on the diagnosis of gynecologic disease. Diverticulitis was established at laparotomy or on roentgenologic examination. Treatment was with antibiotics, salazopyrine, and diet. The patients continue free from symptoms after 2 years.

Fetomaternal Leukocyte Incompatibility. R. Payne and M. R. Rolfs. J. Clin. Invest. 37:1756-1763 (Dec.) 1958 [New York].

Isoleukoagglutinins are known to develop primarily in patients who have received many transfusions, but there may also be other stimuli for leukoagglutinin production. Investigators have drawn upon the analogy to Rh antibody formation and have discussed the possibility that fetal leukocyte antigens might act as stimuli to the mother. The studies presented in this paper demonstrate that fetomaternal leukocyte incompatibility may induce leukoagglutinin formation in the mother and suggest that some leukocyte factors, as demonstrated by their corresponding leukoagglutinins, may be genetically transmitted to the offspring. Serums were collected from 3 groups of women. Group 1 included 144 obstetric clinic patients selected with the sole qualification of multiparity; all women had had 4 or more pregnancies. The majority of the women were in the third trimester of pregnancy, while a few were in the second trimester, as it was thought that more easily detectable amounts of antibody might be present in parous women during late pregnancy. Group 2 consisted of 8 patients who were included because they showed varied circumstances in which leukoagglutinins could be found in parous women. The majority of group 2 had Rh antibodies. There was A-O incompatibility between newborn infant and mother in one instance; another patient was referred because of an anemia of unknown origin; and the last had had a febrile transfusion reaction. Group 3, a control series, consisted of 20 healthy women who had never been pregnant and had never received transfusions.

Leukoagglutinins were found in 25 (or 17%) of the 144 multiparous women. They were completely absent in the controls who had never been transfused or been pregnant. The fetus appeared to be the only stimulus for leukoagglutinin production in 18 of the 25 women, since this number had never received transfusions or blood injections. Isoleukoagglutinins of the maternal serums agglutinated the leukocytes of 10 of 12 of the patients' respective newborn infants, and 12 of 13 of their respective spouses, thus suggesting the inheritance by the offspring of the fathers' leukocyte factor. Maternal sensitization to leukocytes appears to develop in a manner analagous to Rh sensitization.

PEDIATRICS

Streptococcal Infection in a School Population: Preliminary Report. D. Cornfeld, G. Werner, R. Weaver and others. Ann. Int. Med. 49:1305-1319 (Dec.) 1958 [Lancaster, Pa.].

Evidence that prompt and continued treatment of streptococcic infections of the throat may greatly reduce the incidence of primary attacks of rheumatic fever has been obtained largely from military establishments, in which groups are at the risk of epidemic transmission of infectious disease, and in which infection may be subjected to epidemiologic studies. The studies presented here aimed to ascertain whether children of school age, the group most vulnerable to rheumatic fever, can be protected from first attacks of rheumatic fever in a manner similar to that found to be effective in military groups. Three schools in south Philadelphia were selected to furnish for study a population of approximately 1,000 children. During the school year, clinical epidemiologic and bacteriological data were obtained from the children and, where indicated from their family contacts. The aim was to determine: (1) the carrier rate of beta-hemolytic streptococci, (2) the rate of clinically manifest streptococcic infection, and (3) the effect of various treatment programs on both the carrier rate and the rate of clinically manifest infection.

In each of the school years, approximately one-half of the children had one or more positive cultures for beta-hemolytic streptococci, regardless of attempts to control carriers by penicillin treatment. The rate of clinically manifest streptococcic infection remained relatively low in all schools, independent of the existing carrier rate or treatment programs instituted. Relatively few of the children with respiratory symptoms had positive cultures for beta-hemolytic streptococci, and even in the group with positive cultures most of the children presented symptoms of undifferentiated respiratory tract illness. Most of the beta-hemolytic streptococci isolated were of group A, but a large percentage of these could not be typed. The poured-plate method of growing streptococci permitted a significantly higher recovery rate than did any enrichment method or direct streaking method tried. In view of the data presented, the authors question the efficacy of the currently popular programs based upon bacteriological culture studies on school children and penicillin treatment for those found to harbor streptococci in their throats.

Spontaneous Perforation of Bile Ducts in Infancy. T. C. Gertz. Ugesk. læger 120:1454-1458 (Oct. 30) 1958 (In Danish) [Copenhagen].

Spontaneous perforation of the bile ducts in infancy is a rare disorder. The first 2 cases of the entity were described by Caulfield in 1936; 8 additional cases have since been published. Spontaneous perforation of the bile ducts in infancy is characterized by mild intermittent jaundice, acholic stools, absence of bile pigment in the urine, gradually increasing distention of the abdomen with ascites, and often bilateral inguinal hernias containing fluid. The case which the author describes in a female infant, aged 4½ months, recently treated in the Rigshospitalet, Copenhagen, is the 11th case to be reported. The spontaneous perforation of the choledochus in this patient probably originated at the age of 5 to 9 weeks. Cholecystocholangiography revealed a perforation in the choledochus. On operation large amounts of bile-colored ascites fluid were found from an abscess under the right liver lobe. The postoperative course after simple drainage of the choledochus was uneventful, and the patient was discharged as well a month later. The disease is usually subacute but can sometimes be acute. In untreated patients it is fatal. It is important to know the disease so that diagnosis can be timely. Operation with simple drainage of the choledochus region has proved curative in most cases. Preoperative cholangiography is a valuable diagnostic aid.

The Development of Prematurely Born Children with Birth Weights or Minimal Postnatal Weights of 1,000 Grams or Less. M. Dann, S. Z. Levine and E. V. New. Pediatrics 22:1037-1053 (Dec.) 1958 [Springfield, Ill.].

The authors report observations on the physical, mental, and social development of 73 children with very low birth weights, born prematurely between

Jan. 1, 1940, and Dec. 31, 1952, who were discharged alive from the premature nursery of the New York Hospital and were examined between October, 1950, and November, 1957. Of the 73 children, 37 were in the statistical birth weight group of from 660 to 999 Gm. (1½ to 2¼ lb.) and 36 weighed 1,000 to 1,280 Gm. (2¼ to 2¾ lb.) at birth, but their weight fell to 1,000 Gm. or less in the neonatal period. At the time of the examination, 32 children had reached the age of at least 4 years, and the oldest child was 10 years old. In 34 families in which there was a full-term brother or sister, 4 years of age or older, these siblings served for comparison. For obvious reasons, these full-term children were not strictly comparable with the premature group, but they had the same parents and essentially the same home environment.

With rare exceptions, physical health of the prematurely born children was good, with a marked paucity of neurological defects. They showed a tendency to catch up in height to normal standards for chronological age, but often not until after 4 years of age. The incidence of eye defects, especially strabismus and myopia, was high. Intelligence quotients showed a wide range from 59 to 142; the average intelligence quotient was 94, and it was significantly below that of 107 found in the 34 full-time siblings examined for comparison. Twelve of the 73 prematurely born children had intelligence quotients below 80; among the 43 of similar birth weight but not available for examination, 19 were known to be mentally retarded, and 5 of these were in institutions. A significantly higher proportion of the children with intelligence quotients above 100 was found among families of higher socioeconomic rating. A suggestive advantage of girls over boys and of white over nonwhite children was noted, though the latter factor was probably secondary to socioeconomic factors. A high incidence of serious maternal complications existed and might well have influenced the outcome, but within the group no relationship was found between lower intelligence quotient and complications of pregnancy and delivery, with the possible exception of toxemia and cesarean section. There was no greater incidence of low intelligence quotient in patients with visual handicaps than in the total group.

An Additional Contribution to the Study of Constitutional Methemoglobin Cyanosis: Description of Two Cases. G. Bono and P. C. Gamalero. Minerva pediat. 10:1076-1082 (Oct. 13) 1958 (In Italian) [Turin, Italy].

The authors report on 2 male children, brothers, 6 and 3 years old, respectively, with cyanosis. Abnormal amounts of methemoglobin were found in the blood of both patients. The condition was manifest on the skin and on the mucous membranes and became marked on fatigue or when the children cried. The first child also presented clubbed fingers, tracheobronchial adenopathy of tuberculous nature, and latent dyspnea; mild dysrhythmia with slow diffused waves was noticed on electroencephalographic examination. Marked erythrocyte fragility was present in both children and in their parents. The patients were treated with large doses of vitamin C given cyclically by intravenous injection and by mouth for prolonged periods of time.

DERMATOLOGY

Treatment of Persistent Acne in Women with 17 Alpha Hydroxyprogesterone Caproate (Delalutin): A Preliminary Report. K. C. Baker. J. Invest. Dermat. 31:247-250 (Nov.) 1958 [Baltimore].

Seventy-six women, between the ages of 15 and 36 years, with acne, 69 of whom had a definite history of premenstrual exacerbation of the eruption, were treated with 17-alpha-hydroxyprogesterone caproate (Delalutin), an esterified derivative of the naturally occurring progestational hormone. The group included patients with 4 different clinical types of acne; a diagnosis of acne vulgaris was made in 37 women, of acne cystica in 19, of acne rosacea in 3, and of acne sebacea in 17 patients. A single dose of 125 mg. (1 cc.) of this long-acting drug was injected deeply into the gluteal muscle between the 14th and the 18th day after the onset of menstrual flow. Injections were given for a total of 2 to 8 months during the course of the study. Standard therapeutic measures in current use had failed to control the manifestations of acne in these patients. A good to excellent response, as indicated by the clearing of existing lesions and by the prevention of new lesions, was achieved as a result of treatment with this progestational agent in 64 of the 76 patients. A single injection of the steroid ester given once a month and repeated 2 to 6 times thus considerably improved the appearance of the skin. In the dosage administered, hydroxyprogesterone caproate was well tolerated. An alteration in the menstrual pattern (with scanty menses) was observed in one patient during the course of therapy. When the hormone injections were discontinued, however, the menstrual flow again assumed its usual characteristics.

The prolonged effect of the progestogenic compound (10 to 14 days) is thought to resemble the sustained action of the continuous endogenous production of progesterone by the corpus luteum. In comparison, free progesterone has a relatively brief effect (2 to 3 days). The availability of hydroxyprogesterone caproate with a prolonged progestational activity makes possible a physician-controlled regimen which maintains a high progesterone level in rhythm with the normal menstrual cycle. The reported data suggest that hydroxyprogesterone caproate should be given an extensive trial either alone or in conjunction with other systemic and local measures as a therapeutic agent in women with persistent acne.

A Localized Outbreak in New York of Tinea Capitis Due to Trichophyton Violaceum: Observations with Special Reference to Mixed Infections of the Scalp. S. A. Rosenthal, D. Fisher and D. Furnari. A. M. A. Arch. Dermat. 78:689-691 (Dec.) 1958 [Chicago].

Infection of the scalp with Trichophyton violaceum is a rare finding in the United States, although it is common in other areas of the world. The observation of 2 species of fungi simultaneously infecting the same scalp is likewise rare. This paper reports on a localized outbreak of tinea capitis due to T. violaceum, with observations on mixed fungous infections of the scalp, in the Willowbrook State School, Staten Island, N. Y. (for mentally retarded persons). T. violaceum was isolated from 44 of 88 subjects with clinical tinea capitis. A surprisingly large number of mixed fungous infections of the scalp was observed. Of 71 subjects with culturally proved tinea capitis, 33 (46%) showed a mixed scalp infection, with 4 of these each yielding 3 species of fungi.

The clinical picture seen in this series of scalp infections with T. violaceum did not usually show the classic, "black dot" type of morphology. Infected areas showed various degrees of scaling and erythema with broken-off hairs several millimeters long. Often normal-appearing hairs were also present in these areas. The source of the T. violaceum outbreak in this state school is unknown. The close personal contact necessitated by institutional life may well be a cause of considerable dissemination of fungous diseases due to species which otherwise rarely produce disease in the United States.

Skin Lesions Caused by Chlorpromazine. W. G. van Ketel, J. J. Morriën and H. H. Lenstra. Nederl. tijdschr. geneesk. 102:1799-1804 (Sept. 13) 1958 (In Dutch) [Amsterdam].

Published reports show that chlorpromazine sometimes produces skin lesions of the cutaneous vascular type, particularly in patients treated with large doses. The epidermis shows no pathological changes, and the skin lesions rapidly disappear after chlorpromazine therapy is discontinued. After recovery it is often possible to resume treatment with chlorpromazine in smaller doses. It has also been pointed out that it is not always necessary to stop the administration of chlorpromazine, for the skin eruption may subside if the dose is only reduced, or even if it is not changed at all. Tests have revealed that exposure to sunlight may intensify eruptions brought on by chlorpromazine.

Cutaneous lesions that result from sensitization to chlorpromazine by external contact present a different problem than the eruptions caused by medication. An allergic contact dermatitis localized chiefly on the fingers and around the eyes may develop in nursing personnel handling tablets or solutions of chlorpromazine. The authors found that 7 of 62 members of the nursing staff in a small hospital had contact dermatitis; in 5 of these patients the dermatitis was due to chlorpromazine, in 1 chiefly to streptomycin, and in 1 to penicillin. The patch test is valuable in the diagnosis of contact eczema. The onset of the contact dermatitis is usually more delayed, but its prognosis is less favorable than that of the eruption resulting from treatment. No general statement can be made with regard to the influence of exposure to sunlight on the contact dermatitis. Although in one patient such exposure caused an exacerbation, in others the lesions developed in winter, and patch tests combined with sun exposure or ultraviolet irradiation could not be carried out. Repetition of sensitivity tests showed a lessening of sensitivity in some of the patients. A study was made of the most suitable concentrations for testing sensitivity reactions. Cross sensitivity for chemically related preparations, notably promazine, could not be established.

THERAPEUTICS

A Study of the Effectiveness of Certain Anorexigenic Agents. J. F. Fazekas, W. R. Ehrmantraut and J. Kleh. Am. J. M. Sc. 235:692-699 (Dec.) 1958 [Philadelphia].

The authors conducted double-blind studies of the anorexigenic effects of phenmetrazine hydrochloride, a combined preparation of dextro amphetamine sulfate and amobarbital, and a placebo. Phenmetrazine hydrochloride and a placebo were given to, and their effects compared in, a group of 106 obese, mentally normal persons, and, in order to obviate insofar as possible the influence of suggestion, all 3 agents were given to, and their effects compared in, a group of 43 obese, mentally deficient persons. The study was terminated after 28 weeks. In both the mentally alert and the mentally deficient persons, there was a significant reduction of weight with phenmetrazine but no significant change during the placebo administration. Subjective undesirable side-effects, which were evaluated only among the mentally normal persons, disclosed no apparent difference between phenmetrazine and the placebo. In the mentally deficient group, the weight loss induced by dextro amphetamine sulfate was similar to that obtained with phenmetrazine. It is postulated that these drugs act primarily in subcortical areas, probably by influencing localized neurohumoral activity. In view of the almost certain influence of the cortex and spinal cord, as well as the subcortex, on appetite, it should not be surprising that there is considerable variability in individual response to anorexigenic agents.

The Clinical Investigation of a Codeine Resin Complex: A Long Acting Analgesic for Oral Administration. L. J. Cass and W. S. Frederick. New England J. Med. 259:1108-1111 (Dec. 4) 1958 [Boston].

The search for an improved analgesic that can provide effective and sustained relief of pain without appreciable side-effects prompted this study. Experiments in animals have shown that the toxicity of codeine is substantially reduced when it is administered as an ion-exchange resin complex, and also that the analgesic action of the resin complex is potentiated by the addition of certain amines that in themselves have little or no pain-suppressing activity. It seemed desirable to undertake an evaluation of several formulations of the codeine resin complex with other compounds and compare them with a standard preparation, such as mixtures of codeine and acetylsalicylic acid, phenacetin and caffeine citrate.

Eleven analgesics were evaluated in 3 separate clinical experiments on 65 patients with various painful conditions, their ages ranging from 40 to 60 years. Data obtained from a total of 24,640 observations showed that the codeine-methyl-ortho-tolyl-quinazolone resin complex is an effective, long-acting analgesic, in which the synergistic action of the quinazolone derivative makes it possible to reduce the daily total dosage of codeine required to control moderate pain. It was demonstrated that this drug has a greater pain-suppressing effect—for 12 hours after a single dose—than standard codeine combined with acetophenetidin, aspirin, and caffeine.

Experimental and Clinical Research on the Action of Soybean Oil on Cholesterolemia. R. Wolff, R. Herbeuval, G. Cuny and others. Presse méd. 66: 1706-1708 (Nov. 1) 1958 (In French) [Paris].

Alimentary lipids play a large part in the regulation of cholesterolemia. Recent studies have distinguished the action of fats of vegetable origin from that of fats of animal origin. The suppression of animal fats and generally fats rich in saturated fatty acids lowers the level of blood cholesterol. Vegetable oils introduced into the diet in about 40 to 50% of caloric needs exert a hypocholesterolemic action. This action is related to the richness of the fats in unsaturated fatty acids. It is not as yet agreed as to the nature of the unsaturated fatty acids responsible for lowering the cholesterol level. The unsaturation of oils is due to the presence of fatty acids in one or several combinations. These combinations are measured by the iodine index. It was found that the iodine index of soybean oil is high (higher than that of corn oil). Soybean oil contains 4% of vegetable sterols of the beta-sitosterol type. This sterol exerts a hypocholesterolemic action in rabbits and in man by checking the intestinal absorption of cholesterol of exogenous origin. A priori, soybean oil is susceptible of having a hypocholesterolemic action by its degree of unsaturation and by its richness in beta-sitosterol.

The action of soybean oil from the experimental and clinical viewpoints was studied in the laboratory of biological chemistry and in the clinic for diseases of older patients at the Medical School of Nancy. Five lots of 6 to 8 rabbits were given a special feeding with 3 ml. of soybean oil per kilogram of body weight for a period not exceeding 8 days. After this administration there was noted a drop in the level of blood cholesterol, which reached 23 to 31% of the initial value and occurred as early as the next day. Research on man was carried out by studying 15 men whose ages ranged from 50 to 70 years. All except 2 had different manifestations of arteriosclerosis. Nine had arteriosclerotic fundus oculi, with lesions of the capillaries in the retina and cholesterol deposits. Six had arterial hypertension. At the beginning the level of blood cholesterol was high in all subjects—from 2.42 to 4.50 Gm. They were put on a diet with the administration of 1.5 cc. of soybean oil before each of the 2 main meals. In 6 subjects for whom the diet was of short duration (6 to 11 days), a constant fall in the level of total cholesterol was noted. The average fall was to 16% of the initial value. In 9 subjects the administration of soybean oil was of long duration (an average of 63 days). The findings regarding cholesterol level in this group were heterogeneous and difficult to interpret. Despite the presence of large amounts of unsaturated fatty acids of the "essential" type in soybean oil, the action of this oil on cholesterolemia is questionable. Factors other than the unsaturation of fats must intervene in the regulation of blood cholesterol.

An Inter-Relationship Between Ascorbic Acid and Cyanocobalamin. E. V. Cox, R. Gaddie, D. Matthews and others. Clin. Sc. 17:681-692 (Nov.) 1958 [London].

Deficiency of cyanocobalamin, vitamin B_{12}, is closely associated with megaloblastic anemia, and a deficiency of ascorbic acid gives rise to scurvy. The authors cite previously reported observations that suggest an association between these two vitamins, but as yet definite evidence of this in an adequate number of patients is lacking. The investigations reported in this paper were undertaken to determine whether there was indeed any relationship between B_{12} and ascorbic acid. The effect of B_{12} administration on the plasma concentrations of ascorbic acid before and after an intravenous injection of 250 mg. of sodium ascorbate was studied in patients with pernicious anemia, in adults with celiac disease, and in patients with regional ileitis. The patients with low serum B_{12} levels had significantly lower plasma ascorbic acid levels than normal controls.

The rate of disappearance of the injected sodium ascorbate was increased in the state of vitamin B_{12} deficiency—in patients with pernicious anemia, 38.7%; in adults with celiac disease, 39.3%; and in patients with regional ileitis, 36.0%—compared with 24.4% in healthy subjects. After B_{12} therapy the abnormal ascorbic acid metabolism was corrected in patients with pernicious anemia and improved in adults with celiac disease. No change was noted in those with regional ileitis. The effect in pernicious anemia and in celiac disease of adults was masked in those partaking of diets containing a plentiful or a grossly deficient supply of ascorbic acid. In regional ileitis, the lack of effect of B_{12} was attributed to the activity of the underlying disease; a significant correlation was noted between the levels of seromucoids and plasma ascorbic acid. The effect of B_{12} deficiency on ascorbic acid metabolism was greater when the deficiency was associated with a megaloblastic anemia in patients with pernicious anemia and celiac disease of adults than it was in similar patients with a normal erythropoiesis.

Folic Acid and Cyanocobalamin in Pernicious Anaemia. E. V. Cox, M. J. Meynell, W. T. Cooke and R. Gaddie. Clin. Sc. 17:693-699 (Nov.) 1958 [London].

The observation that vitamin B_{12} deficiency can occur without megaloblastic anemia has been noted repeatedly, and it is difficult to explain the hematopoietic defect of pernicious anemia solely on the basis of B_{12} deficiency. A deficiency of folic acid would appear to be of little therapeutic significance, since supplementary folic acid is rarely required in pernicious anemia. The therapeutic activity of folic acid and the lack of anemia in some patients with B_{12} deficiency, however, indicate the possibility of a relationship between these compounds. In this study the authors investigate the metabolism of folic acid in pernicious anemia and observe the effect of B_{12} therapy. Folic acid (5 mg.) was given intramuscularly to 20 normal subjects, 23 hospital patients with no evidence of neoplasm or renal disease, 10 patients with pernicious anemia in relapse, and 10 with pernicious anemia in remission. The urine was collected for 24 hours after the test dose, and an aliquot of each specimen was assayed in duplicate with Streptococcus faecalis to estimate the folic acid content.

The patients with pernicious anemia in relapse were given test doses of folic acid, and the urinary excretion of folic acid was determined on alternate days over a period of at least 14 days. Giving the test dose on alternate days prevented significant overlap in the increased urinary excretion of folic acid. The administration of cyanocobalamin (250 or 1,000 mcg. given intramuscularly daily for 10 days) was commenced in 8 patients after the third folic acid injection and after the first injection in the other 2. The high dosage of vitamin B_{12} was given to obtain saturation as soon as possible. These experiments were controlled by performing similar folic acid excretion tests on alternate days in 3 normal subjects and in 2 patients in complete remission induced by vitamin B_{12}. Two patients with pernicious anemia were studied in the same way as the other patients with this disease, but, instead of folic acid, test doses of 3 mg. of leucovorin (folinic acid) were used. The urinary excretions of folic acid and folinic acid were assayed with Str. faecalis and Leuconostoc citrovorum together with a differential assay.

The results of the various tests are presented in tables, including the excretion of material with only folic acid-like activity (pteroylglutamic acid [P. G. A.]) and that assayable with L. citrovorum (citrovorum factor [C. F.]) in the 2 patients given leucovorin test doses. Summarizing their observations, the authors say that, with a folic acid excretion test, evidence of a deficiency of folic acid was found in 5 out of 10 patients with pernicious anemia. The degree of unsaturation appeared to be slight, and probably does not contribute to the dyshematopoiesis of pernicious anemia. In patients treated with cyanocobalamin, a reduced excretion of P. G. A. and C. F. occurred after administration of either 5 mg. of folic acid or 3 mg. of leucovorin. The changes in the nature and rate of the hematopoiesis were not solely responsible for this fall, since in all but 2 patients they occurred after the reticulocyte peak.

Failure of Ristocetin Therapy in Three Cases of Staphylococcal Sepsis with Bacteremia. L. A. Rantz and E. Jawetz. New England J. Med. 259:963-966 (Nov. 13) 1958 [Boston].

Ristocetin is a new antimicrobial agent produced by Nocardia lurida, of large molecular size and active against gram-positive bacteria. It has been stated to be effective in the treatment of enterococcic and staphylococcic endocarditis. The manufacturer's brochures suggest that it is bactericidal for staphylococci and that patients with severe disease caused by these organisms may be expected to benefit from its administration. Studies in vitro by one of the authors, described here, and by others previously demonstrate that this is not a bactericidal drug, and very few published data are available to substantiate its clinical efficacy. The authors present the histories of 3 patients with staphylococcic sepsis with bacteremia whom they treated with ristocetin. Bacteremia persisted in each during therapy, and clinical improvement failed to occur. The serum of 2 patients was bacteriostatic and bactericidal for the causative organism at the very time that it could still be isolated from the blood. Clinical improvement did not occur in any patient, and in one there was a substantial deterioration in the condition while 2 Gm. of ristocetin was being administered daily.

These treatment failures in patients with infections caused by staphylococci apparently as sensitive to the action of ristocetin in vitro as strains examined by other investigators, and, in fact, inhibited and killed by the serum of the patients during treatment, suggest that a serious and unknown defect in the mode of action of this drug must protect the micro-organism from its effects. It was first thought that this might be due to serum binding, but this could not be demonstrated in vitro. The complete failure of response in 3 patients with staphylococcic sepsis does not suggest that it will be of great value in the management of this disease. Better results were obtained in each case by appropriately selected combinations of other antimicrobial agents, and the infection was eradicated in 2 by this technique.

The Treatment of Constipation with the Use of Antibiotics. A. Ravina. Presse méd. 66:1649-1650 (Oct. 25) 1958 (In French) [Paris].

The author found that several antibiotics, especially tetracycline and neomycin, had results superior to those of ordinary laxatives in the treatment of constipation and can even cure it. Posology is related to results obtained. The author suggested 1 Gm. of tetracycline daily for 5 to 7 days, 500 mg. for the same length of time, and then 250 to 500 mg. twice a week. Effects were usually seen 3 or 4 days after the beginning of treatment. It was rarely necessary to continue treatment for more than a month. Other antibiotics used were Rovamycin (in moderate initial doses), Oleandomycin, Cathomycin, Aureomycin, and Terramycin. When diarrhea occurred, 5 to 10 Gm. of bismuth subnitrate and small amounts of antispasmodic drugs were added to the treatment. Antibiotic medication for constipation was well tolerated. Long experience showed that fears of digestive disturbance due to bacteriolytic substances and of the appearance of a microbial resistance which could impair the action of antibiotics in case of serious infections were groundless. Doses were small enough so that digestive disorder rarely followed. The types of constipation that accompany acne rosacea and dolichocolon or megacolon were especially responsive to this treatment. Cures were complete and prolonged. Even after a short-term antibiotic treatment the volume of feces was considerably increased in a large number of cases.

Further research is needed to define the mode of action of this antibiotic therapy. It is suggested that the effect is due to a modification of the intestinal peristalsis in those patients who have a more serious colonic stasis than was presumed. The author believes that the explanation can more reasonably be based on profound modifications of the intestinal flora.

PATHOLOGY

Hemorrhagic States Secondary to Intravascular Clotting: An Experimental Study of Their Evolution and Prevention. G. D. Penick, H. R. Roberts, W. P. Webster and K. M. Brinkhous. A. M. A. Arch. Path. 66:708-713 (Dec.) 1958 [Chicago].

The paradoxical sequence of clotting followed by hemorrhage develops in certain hemorrhagic complications of pregnancy, surgical trauma, burns, etc. This investigation was conducted to determine whether animals with comparably defective clotting system would be protected from the effects of intravenously administered thromboplastin. The responses of these animals to injected thromboplastin were compared with those of normal control dogs. Crude tissue extracts, which are regarded as "complete" thromboplastin, were injected into 2 normal and 2 hemophilic dogs. Shortly all the animals exhibited minor convulsive movements, hyperpnea, cyanosis, nystagmus, and excessive salivation. The reaction in the hemophilic dogs was less severe and less prolonged than that in the normal animals. All the dogs exhibited thrombocytopenia, hypofibrinogenemia, hypoprothrombinemia, and depressions in the antihemophilic activity of the plasma. These responses were diminished or were nonexistent in dogs with hypocoagulable blood. A similar reaction took place after injection of ultracentrifuged preparations of thromboplastin, which are regarded as "partial" thromboplastin, into a normal and a hemophilic dog. After injection the normal dog showed signs of respiratory difficulty, hyperkinesis, excessive salivation, and tachycardia. Prothrombin concentration was not appreciably altered in either animal. The fibrinogen level decreased in the normal dog but did not change significantly in the hemophilic dog. Depression in the antihemophilic activity of the plasma occurred in the normal dog. Thromboplastin injection prolonged the prothrombin time of the plasma in 4 other normal dogs; no changes were noted in the hemophilic dog.

Partial thromboplastin was injected into each of 4 dogs treated with bishydroxycoumarin (Dicumarol) and into 2 normal dogs. Both normal animals developed respiratory difficulty, hyperkinesis, tachycardia, and pupillary dilation. The animals treated with Dicumarol showed no overt response. In the normal dogs transient thrombocytopenia, hypoprothrombinemia, hypofibrinogenemia, and secondary hemophilia were manifest. These changes were less pronounced in the animals treated with Dicumarol. Partial thromboplastin was injected into 4 dogs to which chloroform had been administered by inhalation 48 hours earlier. Two normal control dogs were studied at the same time. The normal animals again showed reaction signs similar to those described previously. The chloroform-treated animals, even when given up to 6 times as much thromboplastin as the normal dogs, showed no apparent response. Chloroform administration alone had produced low levels of prothrombin and of fibrinogen and depressed the antihemophilic activity of the plasma in all 4 dogs to about 45% of the levels before chloroform treatment. These findings indicate similarity between the response to injected thromboplastin and the reactions known to occur during in vitro coagulation. They tend to support the concept that the hemorrhagic states in disorders associated with circulating thromboplastic tissue products probably result from widespread intravascular coagulation and concomitant consumption and depression of many clotting factors.

Staphylococcal Infection Resistant to Chloramphenicol, Erythromycin, and Novobiocin: Effect of Antibiotic Combinations on the Emergence of Resistant Strains. M. Barber, A. Csillag and A. J. Medway. Brit. M. J. 2:1377-1380 (Dec. 6) 1958 [London].

In an attempt to combat the adaptability of Staphylococcus organisms to antibiotics, the authors introduced into a large general hospital in London a policy for the control of antibiotics, the essential items of which were abandonment of penicillin, except in certain wards of the hospital, and use of 2 antibiotics in combination wherever possible and always when erythromycin or novobiocin was used. The antibiotic sensitivity of all strains of Staphylococcus pyogenes var. aureus isolated from patients with infectious diseases in the hospital was studied during 6 months before the introduction of this policy in April, 1958, and for 6 months afterwards.

Analysis of erythromycin-and-chloramphenicol-resistant infections showed evidence of cross-resistance between these two antibiotics. Of 23 erythromycin-resistant strains, 11 came from patients who had been treated with chloramphenicol; 8 of the 11 patients had been given chloramphenicol in combination with erythromycin and 3 had received chloramphenicol without erythromycin. Moreover, 8 of the erythromycin-resistant strains also showed resistance to chloramphenicol, although in 2 cases the patient had been treated with erythromycin but not chloramphenicol. No such cross-resistance was noted between erythromycin and novobiocin, and of 108 patients treated with this combination, none yielded a Staphylococcus organism resistant to erythromycin, although from 2 of these patients strains resistant to novobiocin were isolated. These findings emphasize the danger of erythromycin-resistant infection becoming a hospital problem if the unrestricted use of erythromycin is permitted. Since there is evidence of cross-resistance between erythromycin and chloramphenicol, combined treatment with these 2 antibiotics offers no solution. Since novobiocin, like erythromycin, has the defect that staphylcocci readily become resistant to it, both should be used sparingly, and neither except in combination with the other or with another chemotherapeutic agent.

Two Serological Tests for Staphylococcal Infection. A. G. Towers and G. P. Gladstone. Lancet 2:1192-1195 (Dec. 6) 1958 [London].

Serums obtained from 156 patients, 83 of whom had staphylococcic infections and 73 had other infections, were examined for their content of anti-Panton-Valentine (P.V.) leukocidin during the course of infection, and the results were compared with those of anti-alpha-hemolysin tests. Of the 83 patients, 69 had osteomyelitis, 6 had tuberculous sinuses secondarily infected by staphylococci, and 8 had other stapyhlococcic infections. Of the 73 patients, 22 had bone and joint tuberculosis, and 51 had miscellaneous nonstaphylococcic infections. A rise of titer of anti-alpha-hemolysin was found in only 27 (33%) of the 83 patients with staphylococcic infections, whereas the titer of anti-P.V.-leukocidin was raised in 68 (82%) of the 83 patients. On the other hand, 12 (17%) of the 73 patients with other infections had an increased anti-P.V.-leukocidin serum level, whereas none of them had an increased anti-alpha-hemolysin serum level. A combination of these 2 serologic tests is of diagnostic value, particularly in patients with deep-seated infection from whom no organisms have been isolated, because the organisms often multiply in sites from which recovery is difficult, such as spinal lesions.

Seminiferous Tubule Dysgenesis (Klinefelter's Syndrome) in Identical Twins. D. A. Holub, M. M. Grumbach and J. W. Jailer. J. Clin. Endocrinol. 18:1359-1368 (Dec.) 1958 [Springfield, Ill.].

Seminiferous tubule dysgenesis (Klinefelter's syndrome) was proved by testicular biopsy in 17-year-old identical twins who presented with the typical clinical features of the syndrome. Female nuclear chromatin patterns were present in the Leydig cells and in buccal mucosal smears of both patients. The identity of the twins was established by means of reciprocal homografts, blood antigen studies, dermatoglyphics, and the history of a single placenta. The principal theories concerning the etiology of this syndrome are briefly reviewed. It is concluded that concordance for seminiferous tubule dysgenesis in identical twins in the light of previous evidence supports the concept that a genetic predisposition exists in this disorder.

ANESTHESIA

Procaine Sensitivity: The Relationship of the Allergic Eczematous Contact-Type to the Urticarial, Anaphylactoid Variety: The Use of Xylocaine in Procaine-Sensitive Individuals. A. A. Fisher and H. M. Strum. Ann. Allergy **16**:593-598 (Nov.-Dec.) 1958 [St. Paul].

The authors found that allergic eczematous sensitivity to procaine, besides being an occupational hazard of the dental profession, is fairly common in the general population. They found 36 patients who showed strongly positive reactions to patch tests with 2% aqueous solution of procaine hydrochloride. Recently they were able to confirm the observations of others that many individuals who have allergic eczematous sensitivity to products of the group embracing paraphenylenediamine, benzocaine, and para-aminobenzoic acid frequently show cross-reactions to procaine. Since paraphenylenediamine and benzocaine are among the more common and most potent sensitizers, it becomes apparent that procaine sensitivity may become established in many patients who have never had actual topical contact with procaine. In addition, it must be remembered that procaine is the most widely used local anesthetic. While it is generally admitted that procaine frequently causes eczematous contact allergy, there seems to be no agreement as to the frequency with which it causes urticarial anaphylactoid allergy. In this paper the authors describe experiments carried out to obtain more accurate information concerning the hazards of the injection or ingestion of procaine in patients with allergic eczematous contact-type sensitivity to procaine.

Twenty patients with allergic eczematous sensitivity to procaine were subjected to scratch and intradermal tests, subcutaneous injections, and ingestion of procaine. None of these patients showed immediate local wheal reactions to these tests, and none had general urticarial or anaphylactoid reactions. As a rule, it would seem that allergic eczematous sensitivity to procaine is not accompanied by the vascular, anaphylactoid allergy, certainly not to any notably high degree. Xylocaine has proved an excellent substitute for, and does not cross-react with procaine. Dentists with eczematous sensitivity to procaine can use Xylocaine without skin reaction. Although urticarial anaphylactoid sensitivity rarely accompanies eczematous sensitivity to procaine, it would nevertheless seem wise to use Xylocaine for local anesthesia in all persons sensitive to procaine.

Clinical Evaluation of a New Ultrashort-Action Oxygen Barbiturate for Intravenous Anesthesia. R. Weyl, B. Unal and Y. Alper. Surg. Gynec. & Obst. **107**:588-592 (Nov.) 1958 [Chicago].

The authors report clinical observations on 200 unselected patients in whom anesthesia was induced with the new ultrashort-acting oxybarbiturate, methohexital sodium, also known as compound 25398. Chemically it is 1-methyl-5-allyl-5 (1 methyl-2-pentynyl) sodium barbiturate. It is a white crystalline solid which is easily soluble in water. It is stable in aqueous solution at 5 C for 1 year and at 25 C for 6 months. The pH ranges between 10 and 11. Preliminary studies carried out by others on cats, mice, rabbits, monkeys, and dogs showed the compound to be 3 times as potent and one-half as long in action as thiopentobarbital (thiopental sodium) and much less likely to show accumulation. The compound did not produce venous irritation or hemolysis during these animal experiments.

The authors found that in the 200 patients the new ultrashort-acting methohexital sodium provided smooth rapid induction, adequate maintenance, and prompt awakening with the use of either a 1% solution for intermittent intravenous injection or a 0.2% solution for intravenous drip. The required doses of this drug are small as compared with those of the thiobarbiturates. The drug seems to be metabolized quickly. It supplies good jaw relaxation, so that a pharyngeal airway can be introduced early. Laryngospasm did not occur in this series. The compound provided an adequate state of analgesia; this was best achieved by the slow-drip method. The compound could be used in connection with the usual inhalants and relaxants. No convulsions occurred in this series, and no venous irritation was noted at the site of injection. Compound 25398 seems to be a safe agent in the hands of the experienced anesthetist. It deserves further evaluation.

BOOK REVIEWS

Penicillin. By Harold L. Hirsh, M.D., and Lawrence E. Putnam, M.D. Foreword by Harry F. Dowling, M.D. Antibiotics monographs no. 9. Under editorial direction of Henry Welch, Ph.D., and Féliz Martí-Ibáñez, M.D. Cloth. $4. Pp. 148, with 9 illustrations. Medical Encyclopedia, Inc., 30 E. 60th St., New York 22; Distributors outside U. S. A.: Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

The authors of this monograph have imparted a wealth of highly practical information obtained over a 15-year period of firsthand experience with penicillin. The slant of the book is clinical rather than pharmacological. After a brief historical introduction the antimicrobial spectrum of penicillin is discussed. This chapter identifies those areas in which penicillin is of proved value and points out those infections against which it is clearly ineffective and hence not indicated. Practical suggestions are also given for reducing the incidence of hospital-acquired infections due to penicillin-resistant strains of staphylococci. The clinical aspects of the pharmacology and toxicity of penicillin are briefly but competently presented. The chapter on dosage forms contains useful information on the characteristics of the diverse commercial preparations. The remainder of the book is devoted to a discussion of the use of penicillin in specific infections known to respond to its antimicrobial action. Each section is prefaced by a brief characterization of the particular disease and is followed by recommendations as to the preparation of choice, preferred route of administration, and proper dosage. There is a subject index and a bibliography. Since penicillin is used in practically all branches of clinical medicine, this monograph should be a valuable reference source as well as a manual of therapy for all physicians.

Urology in General Practice. By Frank Coleman Hamm, M.D., M.S., F.A.C.S., Professor of Urology, Department of Surgery, State University of New York Downstate Medical Center, Brooklyn, and Sidney R. Weinberg, M.D., F.A.C.S., Assistant Professor of Urology, Department of Surgery, State University of New York Downstate Medical Center. Paper. $6. Pp. 293, with 259 illustrations [drawings] by Elizabeth Cuzzort. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada, 1958.

The authors state that, after using this book for a year in their classes at the State University of New York, they have been encouraged by the response of students and other teachers to make it available for wider distribution. Although the book is paper-backed the print and paper are excellent and the illustrations are clear and instructive. The aim of this book is to introduce the medical student and the resident to the field of urology, and to provide a ready reference in the subject for those in other branches of medicine and surgery. The principles of management presented are generally accepted. The material is well arranged and adequately illustrated. This is one of the best of many similar texts on urology which have been published in the United States in the past three years.

The Ecology of the Medical Student: Report of the Fifth Teaching Institute, Association of American Medical Colleges, Atlantic City, New Jersey, October 15-19, 1957. Edited by Helen Hofer Gee and Robert J. Glaser, with assistance of Planning Committee. Editorial coordination by E. Shepley Nourse. Published as part 2 of Journal of Medical Education, October, 1958. Cloth. $3. Paper. $2. Pp. 262, with illustrations. Office of Director of Research, Association of American Medical Colleges, 2530 Ridge Ave., Evanston, Ill., 1958.

In the introduction to this comprehensive report Dr. G. P. Berry points out that "becoming a good doctor is one of the most difficult things in the world." The Institute on the Ecology of the Medical Student focused attention on the various stresses that influence the growth and development of the modern physician. The first part of the report treats the characteristics of medical schools and medical students, dealing with the diversity of values and objectives in medical education and the implications of this diversity. The need for intelligent planning in medical education is stressed as well as the need for research into personality development in interactions with the medical school environment. The second section points up certain factors affecting medical students such as the educational environment, noncurricular factors, and student counseling.

The third section presents interesting data on sociological contributions to the study of the medical student, presenting the procedures for the sociological study of the value climate of medical schools, a commentary on medical education in the social sciences, and an analysis of the development of professional attitudes and capacities. The final section deals with educational patterns in medicine today. It presents new directions in programs of medical education, traditional as opposed to novel approaches to medical education, and the place of the student in the British pattern of medical education. This report is a storehouse of valuable material of vital interest and concern to educators in general, as well as to those specifically concerned

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

with medical education. At this transitional stage of medical education the sociological contributions to the problem as reported in this volume are of particular importance.

Practical Leads to Puzzling Diagnoses: Neuroses That Run Through Families. By Walter C. Alvarez, M.D., D.Sc. Cloth. $9. Pp. 490. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 39 Parker St., London, W. C. 2, England, 1958.

The author briefly summarizes his purposes and objectives as follows: "In this book I describe the symptoms and the syndromes which I found bothering 574 relatives of the psychotic and the alcoholic and 99 relatives of the epileptic. A number of these troubles appeared in such high percentages of the cases that they represent minor equivalents of psychosis and epilepsy. Certain it is that in the families with a poor nervous inheritance I have kept finding a remarkable amount of chronic and often life-long nervous illness, with constitutional inadequacy, neurocirculatory asthenia, hypochondriasis, unemployability, alcoholism and the habit of illness. I am left with the strong impression that these tendencies to illness are inherited." Even though the author professes his conclusions to be only impressions, his fervor makes him write as though it is an established fact that descendants of families with mental illness and alcoholism pass defective genes for the nervous system to their offspring. Environment is so casually mentioned that one has to retain many reservations regarding the authoritativeness of the context of the book. The author's list of symptoms of the relatives of the mentally ill includes practically every symptom of which patients can complain. He does not compare these with the percentages of these symptoms of which relatives of patients with carcinoma, heart disease, diabetes, or multiple sclerosis might complain. Over half of the symptoms which he lists occurred in 5% or less of the relatives, which hardly seems to be statistically significant. One's primary impression is that the book is medical fiction and has to be read with many questions in mind. It is doubtful that there is enough established fact in the text to be of much aid in resolving the puzzling problems of clinical practice.

Poliomyelitis: Papers and Discussions Presented at the Fourth International Poliomyelitis Conference. Compiled and edited for International Poliomyelitis Congress. Cloth. $7.50. Pp. 684, with 422 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada, 1958.

The Fourth International Poliomyelitis Conference was held in Geneva, Switzerland, in 1957. As was the case after the preceding conferences the demand for a permanent record of the papers and discussions necessitated the publication of this book. It is dedicated to Franklin D. Roosevelt and Prof. Edmond Grasset, both dead. It is to be hoped that the subject itself will enter the realm of past history soon. At this conference interest was centered on vaccination against poliomyelitis, enteric viruses that cause poliomyelitis-like diseases, cultures of mammalian cells, new diagnostic techniques, group and home care of patients with poliomyelitis, and the treatment of the severely stricken. The book is well illustrated with photographs and diagrams. Many of the papers have summaries and lists of pertinent references, and a general summation is presented at the end. The book is well printed and contains an index.

General Ophthalmology. By Daniel Vaughan, M.D., Assistant Clinical Professor of Ophthalmology, University of California School of Medicine, San Francisco, Robert Cook. M.D., Clinical Instructor, Department of Ophthalmology. University of California School of Medicine, and Taylor Asbury, M.D., Assistant Professor of Ophthalmology, College of Medicine, University of Cincinnati, Cincinnati, Ohio. Paper. $4.50. Pp. 328, with illustrations by Ralph Sweet. Lange Medical Publications, Los Altos, Calif., 1958.

From the first pages, where the differential diagnosis of common causes of the inflamed eye is clearly outlined, through the excellent index and selected bibliography the authors present a concise, up-to-date outline of ophthalmology. This work should be of great value in the diagnosis and treatment of eye diseases, not only to the medical student, general practitioner, pediatrician, internist, and resident in ophthalmology but also to the practicing ophthalmologist. The work is authoritative and reveals the skilled hands of Dr. Phillips Thygeson and Dr. Frederick Cordes, to whom the authors give much credit. The chapter on examination is well done and describes some of the more recent methods of diagnostic examination of the eye. Of particular value to the practicing physician is the chapter on the management of common ocular disorders. The sections on ocular emergencies in glaucoma are exceedingly important for the general practitioner. The authors stress the need for the cooperation of physicians in measuring intraocular tension during routine physical examinations in order that much of the unrecognized glaucoma may be diagnosed early and treatment instituted before irreversible ocular damage occurs.

Although there are no colored illustrations in the book, the black and white drawings and photographs are so excellent that except in the chapter on ocular disorder associated with systemic diseases the absence of color is unimportant. The chapter on trauma is brief but excellent and should be read by all who have to deal with ocular emergencies. It is especially recommended to the industrial surgeon. Chapter 13 (on neuro-ophthalmology) gives a brief but valuable outline of the subject which should be helpful to neurologists and neurosurgeons. The publishers have done a fine piece of work but ease and speed of reading might be facilitated if there were two columns to a page. This book is enthusiastically recommended to all who wish a clear, concise review of the essentials of ophthalmology.

Medical Department, United States Army: Preventive Medicine in World War II. Volume IV: Communicable Diseases Transmitted Chiefly Through Respiratory and Alimentary Tracts. Prepared and published under direction of Major General S. B. Hays, Surgeon General, United States Army. Editor in chief: Colonel John Boyd Coates Jr., MC. Editor for preventive medicine: Ebbe Curtis Hoff, Ph.D., M.D. Assistant editor: Phebe M. Hoff, M.A. Office of the Surgeon General, Department of the Army, Washington, D. C. Cloth. $5.50. Pp. 544, with illustrations. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1958.

This volume is a part of the clinical as distinguished from the administrative series on the history of the Medical Department of the Army in World War II. Two previous volumes on preventive medicine have been published. After an introductory chapter by Dr. John E. Gordon there are sections on diseases transmitted through the respiratory and alimentary tracts. Among others Dr. Joseph Stokes contributed chapters on chicken pox, mumps, measles, rubella, and pertussis; Dr. Philip Sartwell one on common respiratory diseases; Dr. Thomas Francis Jr. one on influenza; Dr. Joseph Smadel one on psittacosis; Col. L. A. Potter one on smallpox; Dr. A. C. McGuiness one on diphtheria; Dr. Esmond Long one on tuberculosis; Dr. Dwight Kuhns one on salmonelloses; Dr. Gail Dack one on food poisoning; and the late Gen. R. A. Kelser one on brucellosis. This partial list of contributors gives some idea of the high quality of the work. It is a great pity that we have had to wait so long for this volume and it hoped that the other volumes in this series will appear soon. The book has an index.

Rehabilitation Medicine: A Textbook on Physical Medicine and Rehabilitation. By Howard A. Rusk, M.D., Professor and Chairman of Department of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center, New York, and 36 collaborators. With editorial assistance of Eugene J. Taylor, A.M. Cloth. $12. Pp. 572, with 172 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

Dr. Rusk and co-workers have attempted to cover a broad field within the confines of a relatively small book. They believe that the treatment of almost every type of illness, with the exception of minor injuries and simple acute infections, involves the process of rehabilitation. Part 1 deals with the principles of rehabilitation and part 2 with the application of these principles to specific disease problems. This book can be read with profit by the general practitioner or the specialist. Great emphasis has been placed on readability, and for this thanks is probably due Eugene J. Taylor, who is listed as an editorial assistant. The discussion of the principles of rehabilitation sums up everything the authors have talked and written about since the establishment of their service. It should provide an invaluable point of reference for these ideas, which are now collected for the first time under one cover. The fact that the emphasis on the activities of daily living as the focal point for rehabilitative therapy now seems so simple and familiar is almost entirely due to Dr. Rusk's persistence in forcefully supporting this concept.

The sections on electrodiagnosis and electrotherapy bring together many items formerly widely scattered. The chapter on writing prescriptions for rehabilitative treatment should be required reading for all physicians. The chapter on management of psychiatric problems is also excellent. It is hoped that in future editions the authors will eliminate the extended discussion of such an outmoded modality as ultraviolet ray therapy for the many conditions for which it is now recommended. In the discussion of the goniometer there is an apparently inadvertent omission of the method for determining the center of motion of a joint before attempting to measure the range of motion. The possible error is great when this point is neglected. The format of the book is conventional and attractive. There are many excellent photographs and useful charts.

Cyclopropane Anesthesia. By Benjamin Howard Robbins, B.A., M.S., M.D., Professor of Anesthesiology and Associate Professor of Pharmacology, Vanderbilt University School of Medicine, Nashville. Second edition. Cloth. $9. Pp. 293, with 74 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

This edition comes 18 years after the first. The author believes that this is the time for another unified discussion of the subject since there is an apparent increase in the use of cyclopropane in clinical anesthesiology in the United States. This monograph is a reference work and should not be considered a clinical textbook. Its bibliography is extensive, containing 353 references. After a description of the physical and chemical properties and listing the concentrations of cyclopropane needed for anesthesia and respiratory arrest, 110 pages are devoted to its effect on the circulatory system. This is the most extensive discussion in the book and reviews the literature at length. Other chapters discuss the effects of cyclopropane on the respiratory and gastrointestinal systems, the blood, and other tissues. The chapter on clinical administration includes descriptions of techniques that have been reported in the literature.

The author chose to include a short chapter on the relaxing agents because "the introduction of the relaxing agents in 1942 and the widespread use of one of them at the present time makes the use of cyclopropane even more satisfactory." He found no contraindications to the use of cyclopropane except where the explosion hazard (x-ray or cautery) is encountered and in circumstances where epinephrine will be used. The final chapter discusses the explosion hazard with cyclopropane. This monograph will be used by teachers and advanced students. It will not be of value to medical students or others with little clinical experience with cyclopropane. It is attractively composed and printed.

Chloromycetin (Chloramphenicol). By Theodore E. Woodward, M.D., and Charles L. Wisseman Jr., M.D. With collaboration of Harry M. Robinson Jr., M.D., and others. Foreword by Joseph E. Smadel, M.D. Antibiotics monographs no. 8. Under editorial direction of Henry Welch, Ph.D., and Félix Martí-Ibáñez, M.D. Cloth. $4. Pp. 159, with 19 illustrations. Medical Encyclopedia, Inc., 30 E. 60th St., New York 22. Distributors outside U. S. A.: Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

This book is the eighth in a series of monographs published under the direction of the editors of Antibiotics Annual. The authors have produced a highly readable and selective review of the important studies that have been made concerning chloramphenicol, the first of the broad-spectrum antibiotics. There are chapters on the history, activity, properties, dosage forms and route of administration, side-effects, and the clinical results obtained in various infections. Pertinent information is included on the use of other antibiotics and drugs in chloramphenicol-susceptible infections. There is an extensive bibliography and a subject index. As a whole, this monograph should give most readers a balanced picture of the place which chloramphenicol has come to occupy in the treatment of microbial diseases. It should also be of particular value as a reference to and source of information about the drug.

Myasthenia Gravis. By Kermit E. Osserman, M.D., F.A.C.P., Physician-in-Charge, Myasthenia Gravis Clinic, Mount Sinai Hospital, New York. Cloth. $10. Pp. 286, with 58 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 15/16 Queen St., Mayfair, London, W. 1, England, 1958.

A modern monograph on myasthenia gravis has been needed and is now provided by a physician who has had personal experience with more than 350 cases. Although not a common disease, it is being recognized with increasing frequency and, by its nature, it occupies a central position in the differential diagnosis of neurological disorders. With the decline of poliomyelitis it has become one of the most common causes of respiratory paralysis. The illustrations are clear and pertinent. A large number of references are given at the close of each chapter, and there is an adequate index. In this volume the author provides a comprehensive view of this disorder. Normal and abnormal functions of the neuromuscular junction, clinical features, diagnosis, and therapy by means of drugs and thymectomy all receive detailed attention. Much of the material has been published previously by the author but it is useful to have it collected in one volume. An excellent chapter on pathology is provided by Dr. Harvey Mendelow.

The author has performed a great service, but his conclusion must be accepted with some reservations because he is a therapeutic enthusiast. At the outset he states: "particularly in the last five years, new drugs and techniques of management have given the physician tools with which to make the myasthenic patient lead a more normal life." In discussing one of these new drugs, Mestinon, the author reports changes in the economic usefulness of his own patients and claims that "various clinics report up to 70 to 75 per cent increased clinical improvement (on Mestinon) as compared to Prostigmin," but examination of the reports cited does not bear out this contention. Many workers believe that the administration of the new drugs (Mestinon, Mytelase, or any of various experimental preparations) rarely makes a myasthenic patient significantly better than he was under therapy with neostigmine, which has been available since 1935. The value of the new drugs lies chiefly in the facts that their effects are more prolonged or the side-effects are less pronounced. The latter are usually evaluated according to the patient's statement rather than any objective criteria. The use of these drugs has not appreciably affected the mortality of the disease (15 to 30%), nor have they helped in establishing the indications for thymectomy. The author recommends the use of his edrophonium test to determine whether the patient is receiving adequate medication. This test has been widely accepted as a means of differentiating cholinergic from myasthenic crisis, although it has not yet been subjected to critical analysis or controlled study. Its value is not proved in the present monograph beyond the statement that "it is invaluable." Despite minor reservations of this nature, the monograph should be useful to the internists and neurologists who are responsible for the care of patients with myasthenia gravis.

Acetophenetidin: A Critical Bibliographic Review. By Paul K. Smith, Ph.D., Professor of Pharmacology, George Washington University School of Medicine, Washington, D. C. Monographs of Institute for Study of Analgesic and Sedative Drugs IV. Cloth. $5.75. Pp. 180, with 11 illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

This book presents a critical review of the literature on the well-known analgesic-antipyretic agent acetophenetidin and its major metabolite N-acetyl-*p*-aminophenol (*p*-hydroxyacetanilid), to which the nonproprietary names acetaminophen and paracetamol have been applied. The book includes comments by the author as well as abstracts from the literature and from unpublished data. The main text covers the drug's history, chemistry, fate and metabolism in the body, antipyretic and analgesic actions, other therapeutic uses, effects on blood and other tissues, toxicology, tolerance, and habituation, and a summary. The bibliography and a general index appear at the end of the book. In addition to reviewing data pertaining only to acetophenetidin, the literature abstracted also includes studies of its comparative and/or combined action with such other drugs as aminopyrine, antipyrine, allylbarbituric acid, amobarbital, aspirin, salicylamide, and neocinchophen. This monograph should be of special interest and use to pharmacologists and clinical investigators as a critical guide to previously reported studies of the subject drug.

The Health of a Nation: Harvey W. Wiley and the *Fight for Pure Food*. By Oscar A. Anderson Jr Published with aid from Charles Phelps Taft Memorial Fund, University of Cincinnati. Cloth. $6. Pp. 333, with illustrations. Published for University of Cincinnati by University of Chicago Press, 5750 Ellis Ave., Chicago 37; Cambridge University Press, Bentley House, 200 Euston Rd., London, N.W. 1, England. University of Toronto Press, Toronto 5, Canada, 1958

This book deals with Harvey W. Wiley, M.D., who made a major contribution to the health of the United States. It should be of particular interest to students of the developments which led to the enactment of the laws which now serve to safeguard our food and drug supplies. The problems and controversies which confronted Dr. Wiley are ably presented. The author acknowledges the constructive part played by the American Medical Association and by individual physicians in the struggle to advance the public interest. Dr. Wiley, food adulteration, and claims for the alleged values of some medicines were and still are highly controversial topics. The book is a valuable contribution to an important field of public health history, even though some students may hold that the author's portrayal of Dr. Wiley's dynamic individualism is not all that he deserves.

The Recovery Room: A Symposium. By John Adriani, M.D., Professor of Surgery, School of Medicine, Tulane University, New Orleans, and John B. Parmley, M.D., Instructor in Surgery, School of Medicine, Tulane University. Publication number 340, American Lecture Series, monograph in American Lectures in Anesthesiology. Edited by John Adriani, M.D., Director, Department of Anesthesia, Charity Hospital, New Orleans. Cloth. $4.25. Pp. 123, with 17 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

In this symposium on nursing and administration in anesthesiology the authors discuss, by means of questions and answers, the definitions, purpose, location, physical setup, administration, personnel, equipment, economics, policies and procedures, general patient management, and special problems of the subject. The illustrations are neat and easily read. This book should be available to nurses, interns, and residents in anesthesiology and surgery. It is neatly and simply organized and approaches the problem directly. Probably the greatest value of this book would be to those organizing a recovery room for the first time. Here they would quickly find the answer to most of their questions.

The Care of the Geriatric Patient. Edited by E. V. Cowdry, Ph.D., Sc.D., Director of Wernse Cancer Research Laboratory, Washington University School of Medicine, St. Louis. Cloth. $8. Pp. 438. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

Care of the geriatric patient has become a prominent subject in the medical literature. This monograph begins with five lectures given to the Los Angeles County Medical Association in 1955, with the addition of discussions of various aspects of management of geriatric patients. Generally, it should serve as a reference book for anyone who treats elderly patients. This phase of patient care should be the function of all doctors and should not be classed as a specialty. This book is comprehensive and goes into various subjects thoroughly; indeed, it may embrace too much with regard to the various specialties. It is heartening to see included a discussion of care of the patient in his home because this aspect has heretofore been neglected. There is an excellent chapter on rehabilitation. Although the philosophy of the book is good, it is hoped that it will not make the reader think he has to be a specialist to care for elderly patients. This monograph should be added to the many books on this subject as a reference for the interested physician. One might wish that it were shorter, because it is doubtful that the busy physician will read it as thoroughly as he should.

Temporal Lobe Epilepsy: A Colloquium Sponsored by the National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda, Maryland, in Cooperation with the International League Against Epilepsy. Edited by Maitland Baldwin and Pearce Bailey. Co-editors: Cosimo Ajmone-Marsan, Igor Klatzo, and Donald Tower. Cloth. $15.50. Pp. 581, with illustrations and 1 chart in back pocket. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

It is not long since the temporal lobes, especially the right one, were counted among the more "silent" areas of the brain. Now they constitute one of the more fruitful fields for neurological investigation. Because they excite the interest of specialists in neurology, psychiatry, neurosurgery, anatomy, chemistry, endocrinology, pathology, electroencephalography, psychology, and other fields, there has sprung up in recent years a vast literature dealing with this portion of the brain. It is most valuable to have available authoritative summaries to which one not familiar with the field or without the time for fuller research may turn for information. This book is such a summary. It is a collection of the papers and the discussion presented at Bethesda, Md., in March, 1957. Those taking part in this symposium constituted most of the outstanding investigators in the world who have interested themselves in these problems. Their papers vary from extensive analyses of the material available to them to brief summaries of two or three pages. They represent many different viewpoints and opinions. The papers have been well prepared and are clear and concise. The discussion has been well edited without losing the spontaneity and often the sparkle which must have characterized this meeting. This is not an encyclopedia, but it is an excellent source of information for those who would bring themselves up to date on this subject and also a starting point for further, more detailed reading. The typography and format are good.

Radiology for Medical Students. By Fred Jenner Hodges, M.D., Professor and Chairman, Department of Radiology, University of Michigan, Ann Arbor, Isadore Lampe, M.D., Professor, Department of Radiology, University of Michigan, and John Floyd Holt, M.D., Professor, Department of Radiology, University of Michigan. Third edition. Cloth. $8.50. Pp. 450, with 109 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

In this edition the authors have revised and reappraised certain portions and deleted others to make room for the inclusion of materials on new developments in diagnostic and therapeutic radiology. The book is intended for the undergraduate student of medicine. It presents basic principles and a fundamental understanding of radiology. The authors, using their book at Michigan to teach juniors, have dispensed with formal lectures, thus increasing the opportunity for informal teaching by means of the case method. The acceptance of this book is attested by the demand for this new edition. The first half is devoted to diagnostic radiology and includes well-chosen illustrations. A chapter dealing with the rapidly expanding field of cardiovascular radiology has been added; the section on pediatric radiology has been accorded proper attention; and material concerned with the biological hazards of radiation has been expanded. The remainder of the book dealing with therapeutic radiology has been revised, with the addition of new material concerning the use of radioactive cobalt (Co^{60}) and reflecting the declining use of radiation in the treatment of nonmalignant disease. In the final paragraph of the preface the authors express a hope that this new edition will serve as well as, if not better than, its predecessors. This book is recommended without reservation to medical students and their teachers. The postgraduate student in radiology should also find it useful, particularly if he is training in a teaching hospital.

Polarography in Medicine, Biochemistry, and Pharmacy. By M. Brezina and P. Zuman. With foreword by J. Heyrovsky. Translated from Czech by S. Wawzonek. [English edition revised from second Czech edition.] Cloth. $19.50. Pp. 862, with 319 illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88/90 Chancery Lane, London, W. C. 2, England, 1958.

In this thoroughly annotated bibliography of the literature of polarographic analysis in the fields of medicine, biochemistry, and pharmacy through 1954, theoretical considerations are touched on only briefly as are descriptions and discussions of general instrumentation. The book is intended mainly to serve the practicing analyst as a survey of the published methods and as a laboratory reference text. Most of the methods are given in sufficient detail for the experienced analyst to use without referring to the original work. About half of the references are to non-English language publications. The text is divided into sections covering the analysis of inorganic compounds, including elements and anionic groups, as determined in air, water, soil, drugs, and in plant and animal tissue. Organic compounds are classified by chemical functional group and also as biochemical classes in which are included vitamins, hormones, alkaloids, and miscellaneous steroids. Proteins and enzymes are treated separately. Tables of important buffers and of half-wave potentials are included. The book should be of great value to those engaged in the analysis of materials of biochemical interest who use the polarographic technique.

Muir's Text-Book of Pathology. Revised by D. F. Cappell, C.B.E., M.D., F.R.F.P.S., Professor of Pathology, University of Glasgow, Glasgow, Scotland. Seventh edition. Cloth. $14.50. Pp. 1201, with 733 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-43 Maddox St., London, W. 1, England, 1958.

This new edition of a well-known text is intended primarily to meet the requirements of undergraduate medical students. Accordingly, it follows the established pattern of such textbooks. Disturbances of the circulation; inflammation; nonspecific and specific granulomas; repair and hypertrophy; disturbances of nutrition; retrogressive changes; infection, fever, and immunity; tumors; and etiological factors in tumor growth are discussed in that order. The latter chapters are devoted to special pathology of the body systems. The text is written in a lucid style. In the course of revision the author has rearranged it to incorporate new material. He emphasizes the importance of the autopsy in the teaching of pathology and the absolute necessity for experience gained through this discipline. There is a list of references. This textbook on general and special pathology meets fully the needs of the undergraduate medical student and also serves as an excellent reference source for pathologists in practice.

QUESTIONS AND ANSWERS

REHABILITATION AFTER A HEART ATTACK

To the Editor:—*A 46-year-old patient sustained a mild myocardial infarct. He had pain in the posterior chest wall but did not seek medical aid until a month later, when angina on effort became more pronounced and he complained of "skipped beats" (pulsus bigeminus and pulsus trigeminus). He was hospitalized, maintained on bed rest and quinidine therapy, and discharged after six weeks. He convalesced at home for six more weeks and now has a vocational problem. He has been offered a position 400 miles from his home. This would involve moving his family and reestablishing his home elsewhere early in 1959. He would be required to be available for night work once every two weeks. Would such a change for this patient be considered hazardous?*

M.D., Ohio.

Answer.—This patient presents a problem in rehabilitation. Initially, a month passed before he saw his physician; then he had six weeks of rest at the hospital and six additional weeks at home. He therefore has had about four months of convalescence since his original myocardial infarct. This is a sufficient period for maximum healing. Factors that would limit his activity would be increased heart size, high blood pressure, and exertional dyspnea and angina. Assuming that he has none of these, there should be no reason why he is not physically capable of taking on a new position. The required moving of his family, reestablishment of his home, and occasional night work would have no particular harmful effects. The decision must be based, in large part, on socioeconomic factors, and these are not stated. If a man has experienced a myocardial infarction and has made a fairly satisfactory recovery, there is no reason to treat him as if he were fragile. In terms of his survival, proper diet, proper weight, and adequate activity are far more valuable than oversolicitous medical conservatism.

INHALATION OF PURE OXYGEN

To the Editor:—*How long may man breathe 100% oxygen without injurious effect?*

M.D., California.

Answer.—There now exists a sizable body of information about oxygen intoxication, some of it relating to retrolental fibroplasia and other effects on infants and some relating to the effects of oxygen inhaled under pressures higher than one atmosphere by divers. A normal man can breathe pure oxygen at atmospheric pressure continuously for 14 to 24 hours before developing a mild pulmonary irritation, according to Lambertsen (Respiratory and Circulatory Actions of High Oxygen Pressure, in Proceedings of the Underwater Physiology Symposium, Publication 377, Washington, D. C., National Academy of Sciences–National Research Council, 1955, page 25). Infants are more susceptible to oxygen intoxication, and, according to Everett (*A. M. A. Arch. Ophth.* 56:481, 1956), for all practical purposes there is no concentration of oxygen in excess of that in air that is not associated with risk of developing retrolental fibroplasia. Prolonged action of oxygen in sufficient concentration causes vasoconstriction within the brain and inhibits certain enzyme systems, in addition to the local effects on pulmonary epithelium. In mice, a striking effect on length of life is seen at a critical concentration of oxygen near 70%. Living continually in atmospheres of 20 to 70% of oxygen has little effect on the length of life of the laboratory mouse, but Gerschman and co-workers (*Am. J. Physiol.* 192:563, 1958) found that at concentrations between 70 and 100% there is a critical point that cannot be exceeded without markedly shortening the life of the mouse.

SENSITIVITY TO LIGHT

To the Editor:—*Several years ago when sun lamps were popular, a man now in his 60's used his sun lamp quite often with the result that he not only has what resembles an x-ray burn but also has become sensitive to sunlight and even fluorescent light and television light under certain conditions. Even his office is free from sunshine. All medical evaluation otherwise gives negative results. His main complaint after exposure is that he "feels awful" and "all in." Can any preparation be used to protect him?*

M.D., New York.

Answer.—Interpretation of this problem necessitates a complex answer. If sunshine causes the patient to "feel awful," he may be suffering from porphyria of the intermittent-acute or chronic-mixed form. His urine should be examined during an acute attack for the presence of a port-wine color, coproporphyrin, uroporphyrin, porphobilin, and porphobilinogen. If porphyria is present, the ingestion of alcohol should be avoided. Also, under these circumstances the functions of the liver should

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

be investigated by appropriate tests. If the skin shows changes which are equivalent to a chronic radiodermatitis (atrophy, telangiectasia, hyperpigmentation, hypopigmentation, ulceration, keratoses, and epitheliomas), the therapeutic and prophylactic problem is different. In the latter case, the keratoses and epitheliomas should be removed, preferably by surgical excision, as dictated by clinical necessity. Surgical planing would improve the texture and appearance of the skin and would decrease the future formation of malignant and premalignant cutaneous neoplasms. Sun screens may assist in preventing further degeneration of the skin, especially after dermabrasion. An antimalarial preparation (250 to 500 mg. of chloroquine one to four times a day by mouth) may decrease photosensitization. Avoidance of sunshine, as far as is practical, should be practiced. Mechanical protection, such as the wearing of a hat and long sleeves, is to be recommended even during overcast weather. Sunbathing and exposure to reinforced solar radiation near bodies of water is contraindicated.

TRANSFUSIONS FOR PATIENTS WITH CANCER

To the Editor:—*This question relates to giving blood to patients entering the hospital in terminal or near terminal stages of carcinomatosis. These patients are not suffering any blood loss from acute gastrointestinal, pulmonary, or uterine hemorrhage. For example, a 52-year-old woman was admitted to the hospital with multiple osseous metastases. Four years previously she had a radical breast amputation for carcinoma. She had x-ray therapy after this operation. During a 14 weeks' stay in the hospital, she received 6 pints of blood. In another instance, a 77-year-old man was admitted to the hospital with severe anemia from carcinoma of the stomach. He received 5 units of blood but died 11 days after admission. Another man, aged 73, was admitted with carcinoma of the colon with metastases; he also had diabetes and hypertensive heart disease. He received 4 units of blood but died eight days after admission. Are blood transfusions indicated in such patients?*

M.D., Illinois.

Answer.—In this setting transfusions are considered as symptomatic or palliative treatment. Therefore, if the patient has symptoms reasonably attributable to anemia per se and if the anemia cannot be corrected by some other means, transfusions are indicated regardless of the patient's poor prognosis. Since the degree of anemia which will produce symptoms depends on the patient's activity and a number of other factors, the evaluation of the need for transfusion should be based on bedside observation rather than any arbitrary hemoglobin value. Patients with anemia due to disseminated cancer, not complicated by blood loss, characteristically have only a moderate anemia which is usually asymptomatic, particularly in those patients whose activity is limited. Most such patients, therefore, are not perceptibly benefited by transfusion. From these statements, it may be seen that the question of whether transfusion therapy was indicated in the cases cited cannot properly be evaluated without knowing more details of these patients' symptoms. It should be emphasized, however, that patients with incurable cancer deserve as careful and considerate symptomatic or palliative treatment as patients ill with non-neoplastic diseases.

LENSES FOR RETINITIS PIGMENTOSA

To the Editor:—*Will any type of lens allow vision from various parts of the retina in patients with retinitis pigmentosa?*

O. C. Amstutz, M.D., Irvine, Ky.

Answer.—There are no lenses especially designed or particularly adaptable for patients with retinitis pigmentosa. Lens systems are designed for eyes that have unusual optical disorders that cannot be corrected by single-piece lenses such as are worn in the usual spectacle frame. The result is an enlarged image on the retina that is helpful in patients with central retinal defects in providing vision in ordinary light. In persons with retinitis pigmentosa, central vision usually remains after peripheral areas of the retina become insensitive to light; consequently, an enlarged image does not materially improve vision. Colored lenses are helpful only in reducing glare or protecting the diseased and impoverished retinal elements from excessive light. The qualified answer to the question is "no."

FEATHERS AND SCALES

To the Editor:—*Prof. P. E. Raymond (Prehistoric Life, Cambridge, Mass., Harvard University Press, 1939, p. 184) has stated: "The scales in fish and the feathers in birds arise from different layers of the skin." Is this correct?*

John R. Howitt, M.D.
Port Arthur, Ontario, Canada.

Answer.—Professor Raymond's statement is correct. Earlier descriptions in comparative anatomy often created artificial series of analogous rather than homologous structures. Fish scales, whether of shark, sturgeon, or trout (placoid, ganoid, or cycloid types of scales, respectively) are derivatives of the dermis. The epidermis of fishes is very thin and never cornifies, and the scales remain embedded in the dermis. In sharks the teeth are modified scales. During the development of a feather there is a transitory dermal papilla which degenerates into the nonliving pulp. Barb and barbules originate entirely from epidermal cell columns which cornify. A feather, therefore, represents a complex modification of the epidermis. The presence of a dermal papilla during the development of fish scales and of feathers probably led to the mistaken identification of such structures. Even a down feather is not an "elongated and frayed out scale."

Scales of reptiles and those on the legs of birds, however, are of epidermal origin. In these animals they represent a thickened stratum corneum and more nearly resemble feathers than do the scales of fishes.

INDURATED SCAR

To THE EDITOR:—*About six weeks ago, a 14-year-old boy received a minor bruise in his upper lip. There was some exudation and slight bleeding at the time, but in a week all external evidence of the injury disappeared. There is, however, a definite area of scar tissue, flat and pea-sized in diameter, that has persisted in size and consistency. There is no possibility of foreign body. A similar scar was removed recently from another patient in the belief that it was a foreign body, but it recurred two weeks later. The scar tissue is not painful, but the boy is a capable cornetist and his teacher has advised him not to play his instrument or any other instrument involving the use of the lips until all evidence of this injury disappears. Is there anything that might speed his recovery?*

Louis H. Bos, M.D., Rehoboth, N. Mex.

ANSWER.—From the description given there was no evidence of a break in the skin of the upper lip. If there was such a break, the wound has apparently healed by secondary intention, leaving a scar both on the skin surface and in the subcutaneous tissue. It is not uncommon for such a scar to continue to be felt for three to six months after all external evidence of injury has disappeared. Some people are more subject to hypertrophic scarring than others. The softening of the scar might be hastened in its early stages by gentle massage with some such substance as cold cream or cocoa butter. It is questionable whether such a procedure would be of any value at this late stage, but the scar should become soft in time, permitting the boy to return to his cornet playing.

CORAL POISONING

To THE EDITOR:—*What is the cause and treatment of "coral poisoning" (infected abrasions from coral)?* *D. D. Dieter, M.D., Eustis, Fla.*

ANSWER.—Coral cuts are generally the result of brushing against or carelessly handling the sharp exoskeletons of various species of stony corals—members of the Coelenterata, order Anthozoa. The severity of the lesion depends on such factors as degree of laceration of the skin, introduction of foreign substances into the wound, venom from the stinging tentacles of the coral polyp, and secondary bacterial infection. Treatment consists of prompt cleansing of the wound, removal of foreign particles, débridement if necessary, and application of antiseptic agents. In severe cases it may be necessary to give the patient bed rest with elevation of the limb, kaolin poultices, dressings of magnesium sulfate in glycerin solution, and antibiotics. A detailed discussion of coral cuts is given by Halsted (Dangerous Marine Animals, Cambridge, Md., Cornell Maritime Press, 1958).

TRACHEAL SCLEROMA

To THE EDITOR:—*What is the latest treatment for scleroma of the subglottic area of the trachea?*

Phelps P. Luria, M.D., Far Rockaway, N. Y.

ANSWER.—Scleroma is a chronic granulomatous disease which may affect any part of the respiratory tract. The diagnosis is based on cultures and biopsy specimens revealing the Fritsch bacillus (Klebsiella rhinoscleromatis), Russell's bodies (nonspecific eosinophilic masses thought to represent degenerated plasma cells), and the characteristic Mikulicz's cells (foamy abundant pale cytoplasm with a relatively small nucleus). Subglottic infiltration in scleroma may cause respiratory obstruction. Tracheostomy may be necessary if removal of the offending tissue does not alleviate respiratory embarrassment. In the active phase of the disease, treatment with tetracyclines or streptomycin is the current method of choice and represents a notable improvement over previous symptomatic measures. Cessation of activity in scleroma is often followed by scarring and stenosis of the larynx or upper trachea. Under these circumstances it is feasible to restore the lumen by removal of scar tissue and to insert a skin graft which can be maintained in position by some type of mold until healing has taken place.

SMALLPOX VACCINATION AND TUBERCULOSIS

To THE EDITOR:—*Please give information on the effect of smallpox vaccination on undiagnosed primary tuberculosis of infancy.*

E. P. Dale, M.D., Los Angeles.

ANSWER.—There seems to be no valid contraindication to smallpox vaccination in undiagnosed (or diagnosed) primary tuberculosis in infancy. If there were a concealed risk in this situation it should have been well demonstrated by experience. It was formerly the custom in many communicable disease hospitals to vaccinate all patients on admission. In countries where both smallpox and tuberculosis are prevalent, smallpox vaccination is currently performed without reference to preexisting tuberculosis. In neither situation is there any evidence that vaccinia accelerates the tuberculous process. In the United States, under current conditions the time of vaccination is an elective matter and the infant should be vaccinated when he is in normal health, but there is no reason to fear the existence of undiscovered primary tuberculosis.

TESTS FOR SPINAL FLUID LOSS

To THE EDITOR:—*Please give a list of tests and references for the identification of spinal fluid escaping through basal skull fractures and the nose. Also, please outline the advantages and disadvantages of spinal injections of methylene blue as a test for such a fracture.*

Joseph Catton, M.D., San Francisco.

ANSWER.—Grossly, especially when the patient leans forward, a clear, odorless fluid in quantity may be collected in a test tube. No sediment is evident on standing. The specific gravity is between 1.005 and 1.010. The normal sugar content of the cerebrospinal fluid of fasting persons is between 50 and 80 mg.%. It is necessary only to demonstrate the reduction of copper sulfate in the collected fluid. The collected fluid will contain no mucin or albumin and only an occasional lymphocyte. It is possible to demonstrate the location of a fracture in the cribriform plate by the injection of 3 to 5 cc. of a 0.6% solution of indigo carmine into the spinal canal. A bluish green fluid will make its appearance in the nasal discharge within 10 to 15 minutes.

ALLERGY TO PENICILLINASE

To THE EDITOR:—*A question and answer on allergy to penicillinase appeared in* THE JOURNAL, *Dec. 20, 1958, page 2207. I initiated the original in vivo and clinical studies pertaining to the use of penicillinase in the treatment of penicillin reactions. It is true, since penicillinase is a protein, that allergic reactions may occur after repeated injections of the enzyme, but when repeated injections are needed they are given over a short period during treatment of the penicillin reaction and there would not be time enough for antibodies to develop which would produce an immediate allergic reaction. If a patient received a further injection or injections of the enzyme months later, then a true allergic reaction might become manifest. The reactions to penicillinase referred to in the answer (including fever and chills), which has been described by me as well as by Zimmerman, cannot be classified as allergic. To my knowledge, about six such reactions occurred in about 300 treated patients. This represents more of a Herxheimer type of reaction, but it is still a mysterious entity.*

Regarding the time factor in using penicillinase in immediate reactions to penicillin, it may be said that within 15 minutes after an intramuscular injection of penicillinase no circulating penicillin can be detected and this would hold even for a shorter period if the enzyme is injected intravenously. If a patient dies within a minute or so after receiving penicillin one would mechanically be unable to get the enzyme into the patient in time, but in many immediate reactions patients go into shock and may be maintained with epinephrine and pressure substances for many hours. In this situation penicillinase can be lifesaving by immediately destroying the offending antigen. Concerning the last sentence, that penicillinase "may be of value in delayed reactions," it can be said that it has proved to be of great value in delayed reactions. In many patients the results have been nothing short of dramatic. In two patients with complete anuria for days associated with a penicillin reaction with no response to conventional means of treatment, marked diuresis began as soon as four hours after the injection of penicillinase.

Robert M. Becker, M.D.
3414 Monroe St.
Madison, Wis.

The above comment was referred to the consultant who answered the original question, and his reply follows.—ED.

To THE EDITOR:—*Nothing in the original reply contradicts the correspondent's statement that allergic reactions to penicillinase might develop primarily after repeated injections, and nothing was said to contradict the opinion that the febrile reactions are not allergic. The acute anaphylactic symptoms produced by penicillin are produced by the sudden release of excessive amounts of histamine or other mediators responsible for the shock symptoms. This is the result of antigen-antibody union. After such a release one could presumably destroy all remaining penicillin and yet not prevent a fatal outcome, because the mediators already released are responsible for the shock. The major problem there is to counteract the effect of these mediators (such as with vasodilatation and bronchial constriction) and later to give medication to make the mediators, particularly histamine, inactive by administering antihistamine. This consultant has no objection to the use of penicillinase as long as the physician does not get the impression that it is the first line of procedure in combating anaphylaxis. Epinephrine, aminophylline, and antihistamine, in that order, are far more important. The correspondent takes issue with the use of the term "may." Does he claim that it is of value in all patients with delayed penicillin reactions? If so, both the published reports and my own experience contradict that contention. The fact remains that penicillinase may or may not be of value in treating delayed reactions.*

LIFE-TABLE ANALYSIS OF SURVIVAL AFTER CEREBRAL THROMBOSIS—TEN-YEAR EXPERIENCE

Roger W. Robinson, M.D., William D. Cohen, Ph.D., Norio Higano, M.D., Richard Meyer, M.D.
Gerhard H. Lukowsky, M.D., Robert B. McLaughlin, M.D.
and
Harold H. MacGilpin Jr., M.D., Worcester, Mass.

Factors of possible prognostic value have been sought in the records of 1,018 patients with cerebral thrombosis admitted to three major hospitals of Worcester during the years 1947 through 1956. The initial attack was fatal in 21% of the cases. Of the 737 patients who survived the first episode of thrombosis, 50% died within 4.1 years, while only 18% of a comparable sample of the general population died within that time. The principal cause of subsequent mortality was recurrent vascular disease, which accounted for 85% of all deaths. There were no important differences between those who survived and those who did not survive the first attack in regard to the incidence of coronary disease, diabetes mellitus, and hypertension, but the association of congestive heart failure with cerebral thrombosis was found to carry a poorer immediate prognosis. Additional factors adversely affecting prognosis were severe initial attacks, and early recurrences.

THE INCREASING prevalence of cerebral thrombosis in the United States has created many medical, social and economic problems.[1] General pessimism by many in the medical profession toward patients with this disease has retarded interest in any systematic study of its natural course or therapy to improve the status of patients so afflicted. The present investigation of cerebral thrombosis, with use of life-table analysis, was undertaken to determine the factors influencing survival of patients after an initial episode and to aid in designing experimental therapeutic programs. An adequate study of the life history of patients with this disease requires a highly stable population of adequate size that is traceable to determine survival rates. Worcester, Mass., with a metropolitan population of over 500,000, meets these requirements. It was therefore possible to complete such a study.

Material and Methods

A record review of all patients with a diagnosis of cerebrovascular disease admitted to the Memorial, St. Vincent, and Worcester City hospitals during the years 1947 through 1956 was made. Patients with intracranial and subarachnoid hemorrhage,

---

From the Research Laboratory and Medical Division, The Memorial Hospital, and medical divisions, St. Vincent and Worcester City hospitals.
Read, in part, before the Third World Congress of Cardiology, Brussels, Sept. 17, 1958. Read before the New England Cardiovascular Society, Boston, Jan. 12, 1959.

embolism, and neoplasm were excluded. The clinical criteria used to confirm the diagnosis of cerebral thrombosis were those outlined by the *ad hoc* committee of the National Institute of Neurological Diseases and Blindness, under the chairmanship of Dr. Clark H. Millikan.[2] One thousand eighteen records of patients with definite cerebral thrombosis were available for analysis. Of the patients surviving the studied admission, more than 97% were traced by a public health nurse employed by the Research Laboratory. Survival data and appropriate information from the records were transferred to check-cards for sorting. Facts regarding mortality, survival, recurrence, and severity of initial attack were organized in life-table form, as described by Hill.[3] Deaths from all causes were included, and a few patients lost sight of prior to 1957 were included in those exposed to risk for the recorded years only. For comparison, life-tables were constructed based on the New England white population from the United States Census of 1950,[4] adjusted for age and sex. Patients whose initial episodes of cerebral thrombosis occurred prior to 1947 were excluded. The severity of the initial attacks of the remaining survivors was graded as follows: grade 1—few neurological signs and symptoms without residual disability (grade 1A, minimal signs and symptoms, e. g., monoparesis, monoplegia, aphasia, or cranial nerve signs, and, grade 1B, transitory hemiparesis or hemiplegia); grade 2—some neurological signs and symptoms with minimal residuals; grade 3—gross neurological signs and symptoms with disabling residuals; and grade 4—total, permanent incapacitation and/or death due to cerebral thrombosis.

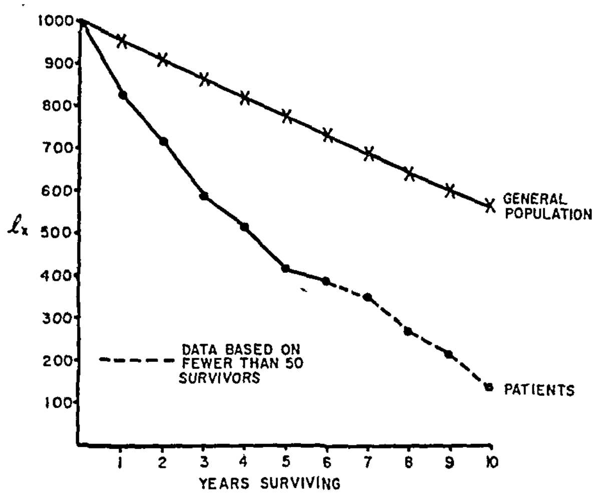

Fig. 1.—Survival of patients with cerebral thrombosis compared to New England population of same age and sex distribution.

Results

Mortality.—A comparison of the mortality among the survivors of an initial attack of cerebral thrombosis with that expected in the New England white population of similar age and sex is shown in figure 1. The abscissa represents years of survival after the first episode and the ordinate (l_x) the number remaining alive at each year, adjusted to 1,000 initial survivors. During the studied admission 196 patients died, an initial mortality of 21%. The lower curve in the figure was derived from records of 737 patients, the 79% who survived the initial attack. It is clear that, within one year, more than 15% of these survivors had died, in contrast to about 5% in the curve drawn for the hypothetical comparable New England population. Fifty per cent of the patients were dead within 4.1 years, while at the same time only 18% of the general population would have died. The five-year mortality of 59%, in contrast to an expected mortality of 23%, shows that these patients are dying about two and one-half times faster than the general population. Beyond the sixth year the data are unreliable, since the calculations had to be based on fewer than 50 survivors. These results are similar to those recently reported by Pincock,[5] but his survival rates were somewhat higher. As this author points out, however, his results cannot be compared with those of patients from an unselected general hospital population because of the all-male veteran character of his group. Also, there were only 101 survivors available for his follow-up study. Another recent report by Pierson and Hoobler[6] showed mortalities of 10 to 15% per year, comparable to those of the present study. However, the selection of hypertensive sub-

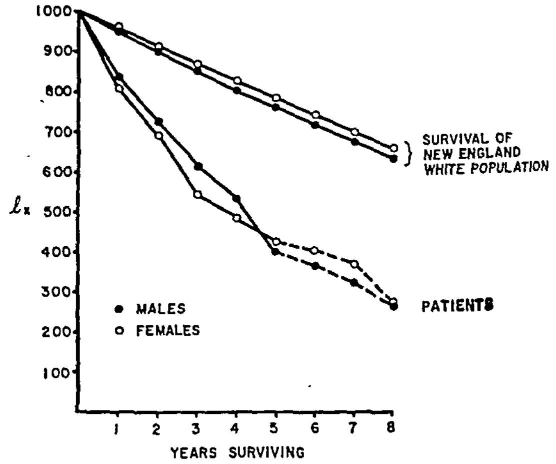

Fig. 2.—Survival of men and women with cerebral thrombosis compared to New England population of same age distribution.

jects under the age of 50 with a previous episode of "focal encephalopathy" restricted this study to an analysis of 71 patients.

Survival.–The similarity of survival rates in men and women is shown in figure 2. The apparent greater survival at three years of men over women does not reach statistical significance, the probability of chance occurrence (p) being about 0.08 by the chi-square test.[7] The average ages of the men (66.2 years) and women (68.0 years) were similar. Although the increased survival rate of women over men in the New England population does not seem great in this figure, these differences are highly significant because of the large size of the studied population.

Despite the similar survival rates of the men and women, a larger number of women were found in the 196 patients who succumbed during the initial episode of the disease. Indeed, of these patients only 36% were males, representing 17% of all males studied, while the 64% of the 196 who were females represented 25% of the women in the entire group. In an attempt to determine the reasons for this greater mortality in women, several pertinent complicating factors were studied, as shown in table 1. Since any sex differences in age and complications were found to be insignificant, the explanation for the difference in mortality remains obscure. This table also reveals that survivors of an initial cerebral thrombosis had a much lower incidence of congestive heart failure (18%) than did those who died (33%)–($p<0.001$). Thus, the association of congestive heart failure with cerebral thrombosis carries a poorer immediate prognosis. There were no important differences in the incidence of coronary disease, diabetes mellitus, and hypertension between those succumbing to and those surviving the initial episode.

TABLE 1.–*Incidence of Complications in Men and Women Who Died at First Attack Compared to Incidence Among Survivors*

	Died at First Attack		
	Males	Females	All Survivors
Patients, no.	66	116	535
Mean age, yr.	69.6	73.6	68.1
Complication			
Coronary disease, %	20	16	21
Diabetes, %	18	17	13
Hypertension, %	68	69	70
Congestive heart failure, %	32	31	18
None, %	17	10	19

Of the 737 patients who survived the initial attack, 344 have since died. The causes of death were ascertained from hospital records (some of which included autopsy reports), death certificates, and, in a few instances, interview of relatives. In table 2 are listed both vascular and miscellaneous causes of death in both males and females. As anticipated, recurrent cerebral vascular disease accounted for 53% of all deaths. This is comparable to the 60% reported by Pierson and Hoobler[8] in their series of 71 patients. An additional 29% of the deaths in the present series were due to coronary disease, with a total of 85% resulting from all vascular causes.

TABLE 2.–*Causes of Death in Survivors of First Attack of Cerebral Thrombosis*

	Male (166 Patients)		Female (178 Patients)	
	No.	%	No.	%
Cerebral	87	52	97	54
Coronary heart disease	46	28	53	30
Renal	4	3	2	2
Peripheral vascular disease	1		1	
Total cardiovascular-renal	138	83	153	86
Miscellaneous	28	17	25	14
Bronchopneumonia	14		10	
Cancer	6		7	
Other	8		8	

Recurrence.–In order to study the relationship between early recurrence of cerebral thrombosis and increased mortality, 535 survivors, all those for whom such information was available, were divided into those with recurrence within two years of the initial episode and those without recurrence during this interval. Since at least a two-year follow-up study was necessary, only patients whose first experience occurred between 1947 and 1955 were included. The two groups were similar in size, age, and incidence of complications, as shown in table 3. The higher incidence of congestive heart failure in the early recurrence group was not statistically significant ($0.05<p<0.10$). But life-table analysis of these patients, shown in figure 3, clearly demonstrates that those with early recurrences had a much higher mortality, with a 50% survival of only two and one-half years, compared with nearly seven years in the group without early recurrence. Thus, these studies provide statistical evidence for the clinical impression that early recurrence is correlated with poor survival. A more detailed analysis of cumulative recurrences after the initial attack

TABLE 3.–*Similarity of Incidence of Complications in Patients With and Without Early Recurrence*

	Recurrence		
	Within 2 Yr.	None Within 2 Yr.	All Survivors
Patients, no.	225	310	535
Mean age, yr.	68.8	67.5	68.1
Complication			
Coronary disease, %	22	19	21
Diabetes, %	13	13	13
Hypertension, %	72	69	70
Congestive heart failure, %	22	16	18
None, %	17	20	19

revealed that over one-third of the patients suffered a recurrence within one year, one-half within two years, and two-thirds by the end of the fourth year.

Severity of Initial Attack.—In order to evaluate the relationship between severity of the initial attack of cerebral thrombosis and mortality, 642 survivors for whom there was sufficient information to grade severity were analyzed by means of life-tables. The tables for grades 2, 3, and 4, all those with residual disability, were combined, since there was no appreciable difference in mortality among them. In figure 4 this combined group is compared with the survivors in grade 1, those without residuals. At three years, the difference in mortality favoring the less severe group (grade 1) was highly significant ($p<0.001$). Since this figure illustrates the difference in mortality between those without and those with residual signs and symptoms, it was of interest to subdivide further the grade-1 group into those with minimal signs and symptoms, grade 1-A, and those with transitory hemiparesis or hemiplegia, grade 1-B. A comparison of the three-year survival rate reveals that group 1-A had only slightly greater mortality than the general population (811 compared with 864 still alive), whereas group 1-B had a mortality nearly comparable to groups 2, 3, and 4 (608 compared with 561 still alive). Thus, despite complete recovery without residual disability, those whose first episodes were more severe and extensive had a much less favorable prognosis than the patients experiencing only mild initial attacks.

Summary

An initial attack of cerebral thrombosis was accompanied by a mortality of 21% in an unselected group of over 1,000 patients admitted to the three major hospitals of Worcester, Mass. Of the 79% surviving the first episode, half had died within 4.1 years, in contrast to an expected mortality of only 18% during this time in the general population, adjusted for age and sex. Although the mortality in women was higher during the initial attack, no sex difference was apparent in long-term survival.

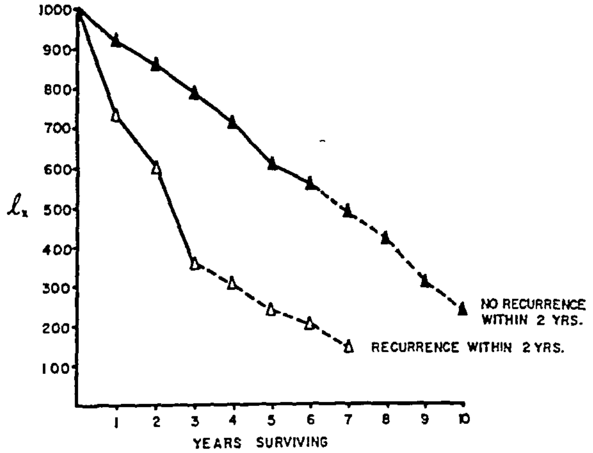

Fig. 3.—Difference in survival of patients with and without early recurrence.

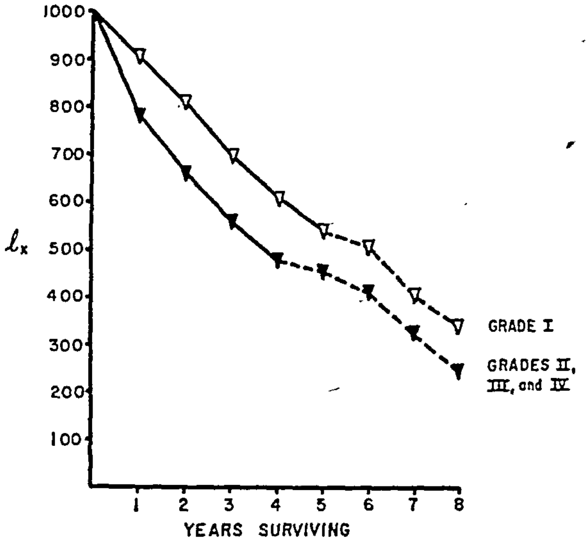

Fig. 4.—Influence of residual disability on survival in cerebral thrombosis.

The principal causes of death in patients surviving the initial attack were recurrent cerebrovascular disease and other vascular disorders, accounting for 85% of all deaths. The three factors that adversely affected prognosis were associated congestive heart failure, more severe initial attacks, and early recurrence of the disease.

TUBE FEEDING

Willard A. Krehl, M.D., Ph.D., New Haven, Conn.

Two types of pabulum for administration by nasogastric tube were studied in nine patients who were unable to swallow. Pabulum no. 1 was made from powdered skimmed cow's milk with the addition of cream, glucose, strained liver, and a vitamin concentrate. Pabulum no. 2 was made by a simple formula from one 15.5-(fluid) oz. (458 cc.) can of commercially available soy bean milk diluted with an equal volume of water and supplemented with the same vitamin concentrate. After a week or more on formula no. 1, all patients had diarrhea. After changing to formula no. 2, five became free of diarrhea within 36 hours. Two of the nine patients did not do well on either formula. Analyses of blood, made in all patients at the beginning and end of a two-week period on formula no. 2, showed no indications of biochemical upsets, and there was no clinical evidence of malnutrition. This simple preparation for tube feeding was tolerated by most patients for at least two weeks with a minimum of gastrointestinal and biochemical complications.

In patients to whom intravenously given fluids can no longer supply adequate nutrition, especially calories and amino acids, tube feeding is often used. Material for tube feeding is formulated so as to provide an adequate level of all nutrients within the range of recommended dietary allowances. Aside from supplying adequate nutrition, tube feeding formulas should fulfill the following criteria: (1) be well tolerated and not induce vomiting; (2) be of proper fluid consistency so as to be easily administered and to supply a sufficient water intake; (3) produce a minimum of gastrointestinal complications, such as excessive flatulence, constipation, abdominal distention, and diarrhea; (4) be easily prepared from readily available and reasonably inexpensive materials; and (5) be homogeneous in composition. Palatability of the tube feeding formula, while not of prime importance, is certainly desirable.

The principal tube feeding formula used in the Grace–New Haven Community Hospital is nutritious and generally satisfactory. However, it does require special preparation by the dietetics department, and in a considerable number of patients it produces soft, loose stools and even frank diarrhea. In an attempt to find a tube feeding formula which might produce fewer gastrointestinal complications, such as diarrhea, and be more easily and quickly prepared on the ward, canned soy bean milk[1] was used in 12 selected patients who had first received the usual tube feeding formula no. 1 (analyzed in table 1).

That soy bean milk might be well suited for tube feeding is evident from the ample support in the literature for its use in the management of conditions involving the gastrointestinal tract, such as peptic ulcer, and as a hypoallergenic food for infants, children, and adults. Balfour[2] has noted that foods used in the treatment of upper gastrointestinal irritation should be easy to digest, should contribute little roughage, and are most effective when given in small, frequent feedings. He has observed further that soy bean milk has been noticeably more soothing than ordinary milk to the upper gastrointestinal tract and is seemingly easier to digest. Burke and co-workers[3] found that soy bean milk is as effective as the Sippy milk and cream regimen insofar as influencing the concentration of gastric acidity is concerned.

Glaser, who has studied the problem of allergy in infants, has had wide experience in the use of soy bean milk as a hypoallergenic food. He has reported[4] the successful use of soy bean milk in over 85% of cases in feeding infants from birth and that this may later be substituted by cow's milk formulas without difficulty, except in those infants in whom there is probably a persistent congenital sensitivity to cow's milk.

Procedure

Nine patients were used in this study, four men and five women, with an over-all age range of 55 to 94 years. Eight of the patients were hospitalized because of severe cerebral vascular accidents, while one patient had postencephalitic paralysis agitans (Parkinson's disease). The latter patient was comatose, was unable to move any extremity, and could not swallow. The other eight patients had hemiplegia and were unable to swallow readily without aspiration. Lumbar punctures were done on all the patients, but only two had red blood cells in the cerebrospinal fluid in sufficient number to indicate bleeding associated with the cerebral vascular accident. None of the patients received anticoagulation therapy. On admission to the hospital, the patients were all given fluids intravenously for periods rang-

ing from three days to one week, and attempts were made routinely to establish whether they could swallow water without aspiration. When it had been established that the patients could not swallow sufficiently well to provide adequate nutrition, the intravenous therapy was discontinued and a nasogastric tube was passed in preparation for tube feeding. Two types of nasogastric tubes were used, i. e., a soft rubber Glenn tube and a small plastic Levin tube. The former tube is preferred because its soft, collapsible, pliable structure minimizes esophageal irritation.

TABLE 1.—*Analysis of Gastrostomy Tube Feeding Formula No. 1**

Ingredients	Amount, Gm.	Protein, Gm.	Fat, Gm.	Carbohydrate, Gm.	Calories
Dry skimmed milk powder	100	35.6	1	52	359
Water	750	...	...	...	...
Cream, 20%	150	4.3	30	6	311
Glucose	10	...	...	10	40
Strained liver	30	4.5	1	...	30
Stress formula vitamin concentrate†	1 capsule	...	...	...	...
Total		44.4	32	68	740

* Calculated on basis of 1,000 ml., with two-thirds calorie per milliliter.

† One capsule supplies thiamin hydrochloride, 10 mg.; riboflavin, 10 mg.; niacinamide, 100 mg.; ascorbic acid, 300 mg.; pyridoxine hydrochloride, 2 mg.; folic acid, 1.5 mg.; calcium pantothenate, 20 mg.; and vitamin B_{12}, 4 mcg.

After the nasogastric tube was passed, nothing was fed through the tube for the first eight hours, except several 50-cc. volumes of water to insure patency of the tube. For the second eight-hour period, saturated lime water was fed through the tube by giving 25 cc. per hour for the first four hours, then 50 cc. per hour for the second four hours. After this, feeding of the gastrostomy formula no. 1 (table 1) was started, first at the rate of 50 cc. per hour for four feedings and then 100 cc. per hour. Thereafter, in a 24-hour period, a total fluid intake of 2,400 cc. per day was given at the rate of 100 cc. per hour, which supplied 1,776 calories and adequate amounts of protein, fat, carbohydrate, and vitamins, as may be calculated from table 1.

Precautions were taken to have suction readily available at the bedside of these patients in the event of regurgitation or aspiration, and they were given careful nursing supervision. Routine blood testing and urinalyses were done, and nonprotein nitrogen, fasting blood sugar, total serum protein with albumin to globulin ratio, and electrolyte levels were determined at intervals throughout the period of study.

The patients reported here developed frequent loose stools after being on therapy with gastrostomy formula no. 1 for periods ranging from one to two weeks. The development of diarrhea greatly magnifies the nursing problem and enhances the chances of urinary tract infection and the development of decubitus ulcers. After diarrhea had developed, stool cultures were made and, in all cases, grew normal flora. Incidentally, none of these patients were treated with antibiotics during the period of the study. After diarrhea had become a troublesome problem for these patients, they were switched from the therapy with gastrostomy feeding formula no. 1 to that with the soy bean milk preparation.

The soy bean milk[1] used was prepared simply and on the ward merely by dilution of a can of soy bean milk with an equal volume of water. To this were added vitamins in the same amounts used for the gastrostomy formula (table 1). The mixture was stored at the bedside in ice until used. One can of soy bean milk so diluted provides 620 calories.

The feedings of soy bean milk were started at the rate of 50 cc. per hour; after a period of three days this amount was increased so that the patients were receiving, each 24 hours, between 2,400 and 2,790 cc., which provided between 1,600 and 1,860 calories with adequate amounts of protein, fat, and carbohydrate, as may be calculated from table 2.

The patients were continued on therapy with the soy bean milk preparation for a period of two weeks, blood testing done, as indicated above, at the start and end of the two-week period. These results are recorded in table 3.

Results

Of the nine patients switched to the soy bean milk therapy, five responded promptly within 36 hours, with a cessation of diarrhea and the passage of no more than two or three soft, but formed, yellow-brown stools. Two patients continued to have more frequent bowel movements, i. e., five or six per day, of poorly formed stools for the first three or four days on therapy with soy bean milk, after which their stools too were reduced in number to two or three per day.

TABLE 2.—*Composition of Soy Bean Milk (Mull-Soy)*

	Undiluted, %	Diluted with Equal Volume of Water,* %
Water	75.0	87.2
Soy protein	6.0	3.1
Soy fat	7.8	4.0
Carbohydrate	8.9	4.5
Crude fiber	0.3	0.2
Minerals		
Total	2.0	1.0
Calcium	0.26	0.13
Phosphorus	0.22	0.11
Iron	0.0004	0.0002
Calories per fluid ounce	40.0	20.0
Calories per cubic centimeter	1.33	0.66

* 1:1 dilution contains 16 mEq. of sodium per liter.

Two of the nine patients did not respond particularly well either to gastrostomy feeding formula no. I or to the soy bean milk. One of these patients occasionally regurgitated the feeding almost as soon as it was given, and great care had to be exercised to avoid aspiration pneumonitis. She also continued to have frequent, loose bowel movements. The other patient had loose, frequent bowel movements which were not altered by the use of soy bean milk but which were reduced in number by the use of paregoric, 5 cc. given four times a day. No patient given either tube feeding preparations showed distention or constipation or developed other gastrointestinal complications.

As can be seen from table 3, the blood chemistry levels remained stable during the period of feeding of soy bean milk. Further, there was no evidence of unfavorably altered clinical status of these patients during this study.

Comment

Although tube feeding is a life-conserving measure which must often be resorted to in patients who are comatose or who are unable to swallow, every possible effort should be used to attempt to get patients to swallow and take nutrients by the normal mechanism before tube feeding is employed. Tube feeding should be patterned to the need of the patient and not to the convenience of the doctor or nursing staff. The most serious and constant threat in a patient receiving tube feeding is the danger of regurgitation or vomiting, because their inadequate swallowing mechanism practically insures aspiration with its undesirable sequelae unless the patient is immediately given suction or positioned to prevent aspiration. For this reason, suction and close nursing supervision should be available for the tube-fed patient.

The experience reported here indicates that soy bean milk diluted 1:1 with water and supplemented with vitamins is a convenient, relatively inexpensive formula for tube feeding which is well tolerated by the patient and produces a minimum of gastrointestinal complications. It is a physiologically and nutritionally sound preparation which has had long and highly satisfactory usage, especially in pediatric medicine. The fact that its preparation is so simple and can be done on the ward by the nursing staff reduces the work of the usually overtaxed staff of the dietetics department. Further, the amount of the tube feeding preparation made at any one time can be small, thus eliminating spoilage, which may become a vexing problem with the usual specially prepared formulas.

It should be pointed out that, while soy bean milk fortified with vitamins and given as reported above is nutritionally adequate within the range of recommended dietary allowances, it is deficient in iron and, when used for a prolonged period of time, should be supplemented with this element. A most convenient form of iron which has been used for this purpose is iron choline citrate complex, prepared as pediatric drops,[a] which contains 16 mg. of elemental iron per cubic centimeter. Two cubic centimeters of this preparation is added for each can of soy bean milk diluted 1:1 with water.

The low sodium content, i. e., 16 mEq. per liter of the 1:1 dilution, provides an ideal dietary regimen when a low sodium intake is also needed in the management of the patient.

Summary

Nine patients in whom tube feeding had been used and in whom diarrhea became troublesome with the usual skim milk–based formula were given a soy bean milk preparation. This is simply prepared by dilution of a can of the ready-prepared soy bean milk with an equal amount of water and fortification with vitamins. The soy bean milk preparation for tube feeding was effective in returning the bowel movement pattern to normal limits in seven of the nine patients.

333 Cedar St. (11).

The soy bean milk preparation used in this study was supplied as Mull-Soy by the Borden Company, Prescription Products Division, New York. The iron choline citrate complex was supplied as Chel-Iron pediatric drops by Kinney & Company, Inc., Columbus, Ind.

The experience reported here indicates that soy bean milk diluted 1:1 with water and supplemented with vitamins is a convenient, relatively inexpensive formula for tube feeding which is well tolerated by the patient and produces a minimum of gastrointestinal complications. It is a physiologically and nutritionally sound preparation which has had long and highly satisfactory usage, especially in pediatric medicine. The fact that its preparation is so simple and can be done on the ward by the nursing staff reduces the work of the usually overtaxed staff of the dietetics department. Further, the amount of the tube feeding preparation made at any one time can be small, thus eliminating spoilage, which may become a vexing problem with the usual specially prepared formulas.

It should be pointed out that, while soy bean milk fortified with vitamins and given as reported above is nutritionally adequate within the range of recommended dietary allowances, it is deficient in iron and, when used for a prolonged period of time, should be supplemented with this element. A most convenient form of iron which has been used for this purpose is iron choline citrate complex, prepared as pediatric drops,[2] which contains 16 mg. of elemental iron per cubic centimeter. Two cubic centimeters of this preparation is added for each can of soy bean milk diluted 1:1 with water.

The low sodium content, i. e., 16 mEq. per liter of the 1:1 dilution, provides an ideal dietary regimen when a low sodium intake is also needed in the management of the patient.

Summary

Nine patients in whom tube feeding had been used and in whom diarrhea became troublesome with the usual skim milk–based formula were given a soy bean milk preparation. This is simply prepared by dilution of a can of the ready-prepared soy bean milk with an equal amount of water and fortification with vitamins. The soy bean milk preparation for tube feeding was effective in returning the bowel movement pattern to normal limits in seven of the nine patients.

333 Cedar St. (11).

The soy bean milk preparation used in this study was supplied as Mull-Soy by the Borden Company, Prescription Products Division, New York. The iron choline citrate complex was supplied as Chēl-Iron pediatric drops by Kinney & Company, Inc., Columbus, Ind.

INTRAVENOUS UROGRAPHY WITH RENOGRAFIN 60%

A REPORT OF MORE THAN 600 CASES

Louis M. Orr, M.D., James L. Campbell, M.D.
and
Miles W. Thomley, M.D., Orlando, Fla.

The reliability and safety of intravenous urography were studied in 654 patients. The injection consisted of 25 cc. of Renografin (a 60% aqueous solution of the methylglucamine salt of 3,5-diacetylamido-2,4,6-triiodobenzoate) given over a period of three minutes; in only three cases were smaller doses used. There were no severe reactions, but vomiting occurred in 11 patients. One of these had a history of allergy, and another had not been properly prepared. The low incidence of reactions was striking because the ages of the patients ranged from 7 to 84 years and 16 had histories of allergy or severe reactions to previously administered contrast agents. Satisfactory roentgenograms of the kidneys were obtained in 636 (97%) of the cases, demonstrating the great diagnostic value of this procedure.

In the 30 years since Osborne and co-workers[1] first attempted to visualize the urinary tract in laboratory animals with intravenously given sodium iodide, intravenous urography has become a widely accepted clinical procedure in urologic diagnosis. According to one estimate, a total of 11,546,000 intravenous urographic procedures were performed in the United States alone from 1942 to 1956, the annual number increasing from 280,000 in 1942 to 1,368,000 in 1956.[2] This remarkable progress within a relatively short time—from laboratory experiment to universally employed diagnostic tool—has come about largely because of the successful development and introduction of new and improved contrast agents.

In 1928 Binz and Räth[3] and in 1930 Swick[4] reported the use of uroselectan after the discovery that selectan-neutral provided good contrast of the kidney, but its use was attended by toxic manifestations. In 1929, uroselectan B (Neo-iopax) was introduced, this being less toxic than uroselectan.[5] Several years later, iodopyracet (Per-abrodil [Diodrast]) was developed, and, for 20 years thereafter, iodopyracet and uroselectan B were commonly used in the majority of intravenous urographic procedures in the United States.[2] More recently, a number of new contrast mediums have been introduced in the United States, the most prominent being perhaps Hypaque and Urokon.

In 1955, a new, organic, tri-iodinated radiopaque compound, identified as Renografin, became available for clinical trial in intravenous urography. After preliminary trials of this material in both the 76 and 60% concentrations, results of which have been reported elsewhere,[6] Renografin 60% has been used exclusively at this clinic for intravenous urography in ambulant patients. Individual case reports have been recorded at the time of examination of each patient, with particular attention to signs of sensitivity or other reaction or vessel pain and to the quality of the urograms obtained with this medium. From April, 1957, to the time of this report, over 600 patients were examined with Renografin 60%. Urograms of diagnostic quality have been consistently obtained with practically no side-effects. The purpose of this communication is to describe briefly our experience with Renografin 60% at this large private clinic during the past year and a half.

Methods and Materials

Patients.—A total of 654 patients is included in this report, 394 male and 260 female. They ranged in age from 7 to 84 years and in weight from 50 to 255 lb. (22.7 to 115.6 kg.). Sixteen patients had a history of hay fever, asthma, or severe reaction to previously administered contrast agents. Each of the 654 patients had presented signs or symptoms of disorders related to the urinary tract or renal pelvis and had been referred to the clinic for diagnosis. The distribution of the patients with reference to age, sex, and weight appears in table 1.

Contrast Medium.—Renografin 60% contains 60% of the methylglucamine salt of 3,5-diacetylamido-2,4,6-triiodobenzoate (diatrizoate) in aqueous solution adjusted to neutrality with sodium hydroxide. The solution contains approximately 29.26% iodine.

Method of Study.—Prior to examination, standard instructions for preparation were given to each patient. Each was advised to take 12 fl. oz. (360 cc.) of magnesium citrate solution 36 hours before coming for examination to eat lightly the day before, and, after midnight, to take nothing by mouth except coffee and toast for breakfast. (Eight patients were examined without such preparation.)

In earlier studies with Renografin, a preliminary test dose of 1 cc. was routinely administered to each patient before examination. In the absence of any reaction whatsoever, use of the test dose was finally abandoned. In fact, none was given to any patient in this series.

At examination, 25 cc. of Renografin 60% was given intravenously over a period of three minutes to every patient, with three exceptions. Only 15 cc.

was given to two boys aged 10 and 13 years, respectively, and 10 cc. was given to an adult patient who had had a severe reaction to a previously administered dye and was apprehensive about the possibility of a similar reaction to Renografin—which did not occur. Films were exposed at 5, 10, and 15 minutes after injection, with the patient erect at the final film. The resulting urograms were evaluated and classified as excellent, good, and fair (there were no poor films), mainly on the basis of the presence or absence of a clear-cut pyelogram in good density, regardless of the age, weight, kidney function, or lack of preparation of the patient.

Results

A summary appears in table 2 of the quality of films obtained with Renografin 60% and the associated reactions encountered. It is evident from this table that good to excellent delineation of the renal collecting system was achieved in 636 of the 654 cases, while only a fair outline was demonstrated in the remaining 18. As anticipated, the greatest proportion of satisfactory films was seen in younger persons of lighter weight. The excretory capacity as a rule is better in younger subjects. Older patients are more difficult to prepare for urographic examination. Moreover, in older persons intestinal gas often obscures and sometimes blocks out kidney delineation even though the dye may be present in the kidney in sufficient concentration to give a good contrast. The quality of films obtained in the individual patients with reference to their respective ages and weights appears in table 3.

Table 2.—*Summary of Results in Intravenous Urographic Examination with Renografin 60%*

There were no severe reactions in any patient in the entire series. A total of 40 patients reported 58 different reactions to the dye, but these reactions were relatively mild and transient in every case. Of the 40 patients with reactions 4 had a history of allergy; 2 had not received the standard preparation prescribed before examination. The incidence of reactions encountered in this study is given in table 4.

Table 4.—*Incidence of Reactions in Forty Patients Subjected to Intravenous Urography with Renografin 60%*

Reaction	Patients,* No.	History of Allergy, No.	Unprepared for Examination,† No.
Nausea	32	2	2
Vomiting	11	1	1
Choking sensations	2	0	
Flushing of skin	8	0	
Tingling of extremities	2	0	
Itching sensations	1	0	
Urticaria	1	0	
Sneezing	1	1	
Total	58	4	8

*Same patient reported one, two, or even three different reactions in number of instances.

†Same patient reported nausea and vomiting in one instance.

Comment

The relatively few and mild reactions encountered in this series is the most striking feature of this study. It is hard to believe that any drug introduced intravenously could be so well borne by so many patients as has Renografin 60% in this large series. The rate of occurrence of reactions is 6%

(40 of 654 patients), which is in accord with the reaction rate reported by others using this medium.[7] Since films of good or excellent quality were obtained in a high percentage (97%) of the cases examined with Renografin 60%, this contrast agent is obviously satisfactory for use in intravenous urography.

Summary and Conclusions

Intravenous urographic examinations have been conducted in a total of 654 patients with use of Renografin 60% as the contrast agent. Satisfactory films were obtained in 636 (97%) without serious reactions to the medium. Mild reactions, such as nausea, vomiting, a sensation of itching, flushing of the skin, urticaria, sneezing, and a choking sensation, were reported by a total of 40 patients.

On the basis of the high percentage of good or excellent films obtained with Renografin 60% and the remarkably few and mild reactions encountered, it is concluded that Renografin 60% is a superior contrast agent for intravenous urography in the ambulant patient.

BRONCHIAL ASTHMA DUE TO FOOD ALLERGY ALONE IN NINETY-FIVE PATIENTS

Albert H. Rowe, M.D., Albert Rowe Jr., M.D.
and
E. James Young, M.D., Oakland, Calif.

The assumption that bronchial asthma is due to inhaled allergens, such as the pollens, has sometimes resulted in overlooking allergens in food. Food allergy has too often been ignored or inadequately controlled when it was the sole cause of bronchial asthma or contributed to the effects of inhaled allergens. Recognition of the importance of food allergy in a given patient is usually impossible unless one begins with a cereal-free elimination diet which assumes allergy to cereal grains as well as to milk, eggs, and other less common allergenic foods. This was clearly demonstrated in 50 children and 45 adults, whose bronchial asthma was relieved without use of antigens, vaccines, corticosteroids, or ACTH. Strict adherence to the diet was necessary at first, especially in the winter, but in many cases it was found that tolerance to some foods developed in one to four years and that a more liberal diet could be allowed in the summer.

Bronchial asthma due to food allergy[1] alone or associated with inhalant allergy is too frequently overlooked. This is due to failure to recognize the typical history of bronchial asthma due to food allergy,[2] especially in children, and its equivalent in adults, including older persons, as summarized below. It also results from the frequency of negative skin reactions to foods causing the asthma[3] and the usual failure of positive skin findings to reveal the responsible foods. Thus, most diets excluding foods giving positive skin reactions fail to control bronchial asthma due to food allergy.[3A] Our realization of the frequency of food allergy therefore has depended on trial diets, of which our cereal-free elimination diet[4] has been most important. Our success has depended on the elimination of all cereal grains, along with milk, egg, chocolate, fish and other less common allergenic foods. Recurrent colds and bronchitis with or without slight wheezing during the fall, winter, and spring months also require similar study of food allergy, as revealed by good results with its use.

Read in the Session on Allergy before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

Our emphasis on food allergy does not detract from the equally important inhalant allergy [5] alone or in association with food sensitization. The role of pollen allergy in asthma limited to the pollen seasons and the importance of animal emanations, house dusts, miscellaneous inhalants, and fungi must be remembered. Positive skin reactions to inhalants, however, do not predetermine clinical allergy. Assurance of such allergy requires long-lasting relief of asthma with desensitization therapy and/or environmental control. Unnecessary and, at times, prolonged ineffectual desensitization to inhalants too often has preceded the relief of bronchial asthma arising from our cereal-free elimination diet.

This increased recognition of food allergy as the cause of bronchial asthma [1a] has minimized possible *bacterial infection or allergy* [5A] as the cause, as reported by Cooke,[6] Chobot [7] and other allergists. The occurrence of viral or infectious colds and bronchitis without resultant asthma [1] when *it is* controlled with elimination of causative foods supports our conclusion that infection is a rare cause of the recurrent bronchial asthma.

Typical History

Recurrent bronchial asthma [8] every two to six weeks, being moderate or severe for one to three days, diminishing in the subsequent one to five days, and decreasing or absent in the summer always suggests food allergy (see figure). It usually starts in the first three years, though a similar or equivalent history occurs in adult life and old age. Initial nasal symptoms suggesting an infectious cold, often with slight fever, generally are wrongly attributed to infection rather than food allergy as the cause. Moderate or severe bronchial asthma then occurs for one to three days with a gradual decrease in one to five days. Fever, due to food allergy, up to 104 F (40 C), is frequent. Anorexia and vomiting may occur. Antibiotics, sulfonamides, and gamma globulin therefore are infrequently justified. Exhaustion of assumed reacting bodies to the allergenic foods terminates the attack. With their regular reaccumulation to the reacting level, attacks recur. Absence of reacting bodies between attacks allows the ingestion of allergenic foods without asthma. If they are not entirely exhausted, slight, interim symptoms may occur. Tolerance for the allergenic foods may develop if the food allergy is controlled for one to four years.

* No antigens, vaccines, corticosteroids, ACTH, or routine antiasthmatic drugs given. Antibiotics and chemotherapy given only for infrequent secondary infections and not routinely during attacks.

†No therapy based on skin reactions.

That infection is not the cause is evidenced by the occurrence of true infectious colds or even pneumonitis with no asthma if the allergenic foods are eliminated. Recurrent colds, with or without coughing and with little or no wheezing, also are often due to food allergy alone rather than infection.

Children.—To emphasize food allergy as a sole cause of bronchial asthma, the statistics in table 1 on 50 infants and children are presented to show bronchial asthma controlled with the elimination of allergenic foods without any injections of inhalant allergens or vaccines and with no corticosteroids, ACTH, antibiotics, or chemotherapy. Many more cases due to food allergy alone are omitted because of brief or longer injections of antigens or vaccines which we now realize were unnecessarily given, largely because of positive skin reactions. A few cases due to food allergy are not included either, because injections of gamma globulin were given and this is of unproved value in asthma.[9] Though antibiotics and chemotherapy are not indicated during attacks of asthma due to food allergy alone, it is justifiable to give such medicaments and respiratory vaccines to help infrequent, secondary infections in such asthma-free persons in all age groups.

The classic or nearly typical history of bronchial asthma due to food allergy is seen to have occurred in 92%. Initial "colds" suggesting infection but due to food allergy occurred in 78%. Antibiotics and sulfonamides had been given ineffectively to some patients for months or years because of assumed infection. Previous fever in 60% and vomiting in 36% did not occur with our control of food allergy. The asthma was decreased or absent in summer in 82%.[10] Slight nasal symptoms in 58% or bronchial symptoms in 36% between previous attacks were relieved with the elimination diet. The former eczema, blood eosinophilia, and recurrent colds were probably results of food allergy. Negative [illegible] in 48%. The [illegible] gave little or no help in our [illegible]. The positive reactions to [illegible] or due to potential [illegible] since the control of food allergy [illegible] relief. Diet history of food [illegible] correlated with the clinical [illegible] in a few patients, especially in cases of [illegible] sensitization. Family histories of prob- [illegible] at times only in aunts, uncles, or grand- [illegible] of asthma or "sinus trouble" oc- [illegible]

[illegible] from parents reflected the importance of the control of food allergy in bronchial asthma in children and indicated that satisfactory results were obtained with the elimination diet alone.

Adults 15 to 55 Years of Age.—The classic history of bronchial asthma due to food allergy occurs in some adults.[11] Usually the asthma is perennial, decreasing or infrequently absent in the summers. Though interim relief between attacks is less than that in children, careful interrogation usually reveals cyclic exaggeration of the chronic asthma, due, in our opinion, to intermittent activation of the causative food allergy. Fever due to food allergy[12] is infrequent in these adults as compared with children. When present, especially if it is prolonged, infrequent secondary infections also have to be considered. The importance of adequate study of allergy in perennial bronchial asthma usually exaggerated from autumn to spring was dramatized in a young woman with such asthma for several years. Finally it persisted without relief from November to March, when a right lower lobectomy was done for assumed questionable bronchiectasis. Because of postoperative infection, decortication of the right lung was necessary after six weeks. The severe asthma continued for four months until our study indicated probable food allergy. With the cereal-free elimination diet, relief occurred in one month and has continued to the time of writing. Such control of food allergy relieved the patient in another case in which lobectomy also had been advised on the basis of questionable x-ray and bronchoscopic findings. As in children, recurrent head and especially bronchial "colds" particularly from autumn to late spring are often relieved with the routine and accurate use of the cereal-free elimination diet, disproving infection as the cause.

* No antigens, vaccines, corticosteroids, ACTH, or routine antiasthmatic drugs given. Antibiotics and chemotherapy given only for infrequent secondary infections and not routinely during attacks.

†No therapy based on skin reactions.

If inhalant allergy, especially pollen, is associated with food allergy, the usual decrease or absence of symptoms in the summer[10] when food is the sole cause may not be observed. Recurrent asthma due to food with more persistent asthma from spring to late fall, moreover, occurs in the same patient.

Statistics on 30 cases of bronchial asthma due to food allergy in adults are given in table 2.

Because of the perennial, usually recurrent, exaggerated asthma, food allergy was studied with our cereal-free elimination diet before any injectants were given. With strict cooperation, relief was evident in one to four weeks. Manipulation of the diet thereafter gradually revealed the foods responsible for the asthma. This stresses the importance of recognizing food allergy and the futility of desensitization and vaccine therapy in such cases. It is rare today, however, that patients with perennial bronchial asthma are not given injectant therapy and that any adequate control of food allergy occurs. In several of these patients, such injections had been given for one to three or more years before our study of food allergy improved or controlled the asthma in one to four weeks.

As in children, skin reactions to foods infrequently correlated with clinical allergies. Moreover, therapy based on the recorded positive reactions to inhalants was not required.

In these adults the average age when first seen was 34.8 years. The age of onset of asthma was 20.8 years. Nasal allergy occurred in 80%. Asthma was worse in the winter in 47%. In the family history, the predominating clinical allergy was bronchial asthma in 40%. Blood eosinophilia occurred in 9.8%.

Adults Over 55 Years of Age.—For many years we have reported bronchial asthma due to food allergy in older patients.[13] Inhalant allergy with or without food allergy has been of similar importance. This refutes opinions of other allergists that inhalant and especially food allergies are rare or even absent, especially after the age of 50 years. In 1947 we reported 173 patients relieved of bronchial asthma who were over 55 years of age.[14] In 82%, food, inhalant, and rare bacterial allergy were causative; 40% were due, in our opinion, to food allergy alone. Thus food and inhalant allergies by our analyses were of equal importance.

In table 3 statistics are presented on 15 patients over 55 years of age with bronchial asthma controlled by the elimination of specific foods alone. This group would have been greater if we, like the majority of physicians, had not given unwarranted injections of inhalants or vaccines because of positive skin reactions or assumed infection. Moreover, cases of asthma exaggerated or occurring only in the fall, winter, and spring which were controlled with the use of our cereal-free elimination diet but in which pollen therapy was given because of active or potential pollen sensitization from late spring to fall are not included. In the last few years we have refrained from such injectant therapy when food allergy seemed to be the sole cause of the asthma and after it was adequately controlled with the elimination diet alone.

Bronchial asthma in 15 patients over the age of 55 years was controlled only with the elimination of allergenic foods. In spite of slight to moderate reactions to inhalants, no injections of antigens or vaccines were given. Asthma had existed for four months to 54 years with an average of 10 years. The age of onset was from 2 to 57 years with an average age of 50 years. Asthma was perennial except in one case. As in the classic history of asthma due to food allergy in children, the asthma was better in 46% and absent in one case in the summer months. There was no complete interim freedom between attacks, though recurrent exaggeration of asthma was evident in the histories of 40%. Improvement occurred in the summer in 40% and in dry, inland areas in 13%.[10] Nasal allergy had occurred in 66%. Drug allergy, especially to aspirin, occurred in 20%. Corticoids and/or ACTH had been given with no benefit to 20% of these patients before they were relieved with our elimination diets. They were not included in our results. Infective and intrinsic causes had been erroneously assumed *in several of these patients.*

Thus food and/or inhalant allergies must be studied in all patients with bronchial asthma in old age. Recognition of cardiovascular and renal disease, emphysema, and other causes of wheezing and dyspnea is necessary, of course, especially in this age group. Complete relief of such cases of bronchial asthma or asthmatic bronchitis, exaggerated or only occurring from fall to spring, minimizes possible infective or intrinsic causes. Only death terminates the development or continuance of such allergies in old age.

Study and Control of Food Allergy

Food allergy requires study when the classic history of bronchial asthma due to food allergy in childhood or similar or less typical perennial histories in adults and old age occur. It is also necessary when food and inhalant allergies are indicated causes.

To study and control food allergy, a diet which excludes foods that give large scratch reactions and/or a history of definite food dislikes or disagreements may be effective. The intradermal method of testing is not used in our study because of the many indefinite or false reactions which arise. Relief infrequently results because of the known fallibility of skin testing,[3A] especially in food allergy, and the frequent failure of diet histories to indicate any or all allergenic foods.

The cereal-free elimination diet[4] is then given, with indicated modifications. Indeed, it is usually used without the initial elimination of foods giving positive skin reactions or a positive diet history.

For good results, strict adherence to the diet is imperative, with maintenance of proper weight and nutrition. Realization that foods remain in the body for several days or longer is important. This, together with the time necessary for the disappearance of changes in the lungs, especially in chronic bronchial asthma, explains the time required for control of symptoms. Because of these facts a moderate attack may occur in one to three weeks after the start of the diet free of allergenic foods. The next expected attack, however, should be absent. If food allergy causes persistent or interim symptoms, some relief may not be evident for 5 to 10 days.

Inhalation of odors of allergenic foods must be minimized or avoided. The absence or decrease of symptoms due to food allergy during the summer and the increase in the fall, winter, and early spring months must be remembered.[10] This usually allows a liberal summer diet and requires a strict winter elimination diet to control the food allergy. Injections of inhalants or vaccines should not be given when food allergy is the probable or proved cause. If the cereal-free elimination diet fails to relieve asthma in three to four weeks, however, then such injections are justified if the history with or without positive skin reactions indicates inhalant allergy. Needless injections of inhalants or vaccines are costly and tend to decrease the importance of food allergy and the required elimination diet in the minds of patient and physician alike.

* No antigens, vaccines, corticosteroids, ACTH, or routine antiasthmatic drugs given. Antibiotics and chemotherapy given only for infrequent secondary infections and not routinely during attacks.

†No therapy based on skin reactions.

Until relief of symptoms occurs from the elimination of allergenic foods or when symptoms recur from breaks in the diet or trial ingestion of causative foods, severe, at times intractable, asthma from food allergy requires epinephrine given hypodermically, aminophylline by vein or rectum, corticosteroids, ACTH, and adequate replacement of fluid and electrolytes. Less severe attacks or persistent symptoms require epinephrine given subcutaneously or by inhalation, aminophylline, ephedrine, and, if necessary, corticosteroids. Other inhalant therapy and, at times, antihistamines, isoproterenol (Isuprel), and iodides may be helpful.

The cereal-free elimination diet should be ordered immediately if the history gives any suggestion of food allergy. If nausea is present, parenterally given fluids and the preparation of the diet in a liquid or soft form are indicated until the appetite returns. The immediate use of the diet will hasten the control of food allergy and the discontinuance of the above medication.

As long as symptoms continue to require medication, physicians are challenged with the study and control of possible allergy to other foods, to inhalants, or to rarer infectants and drugs. Errors in the diet must always be suspected. When inhalant, drug, or rare infectant allergies accompany food allergy or are sole causes, their study and control obviously are necessary. The control of bronchial asthma with antiallergic therapy alone without medication is the physician's responsibility.

Summary

Food allergy as the sole cause of bronchial asthma or associated with inhalant or rare infectant or drug allergy is too often ignored and inadequately controlled by the medical profession. The classic history consists of regularly recurring attacks of bronchial asthma, usually preceded by nasal allergy suggesting an infectious cold rather than the causative food allergy. The attacks recurring from fall to late spring are often associated with vomiting and fever due to food allergy. The asthma decreases or is absent in the summer. It usually starts before the third year, though a similar history may begin in adult life or old age. Interim relief between the attacks is usual in childhood, decreasing in adolescence and in adult life.

The use of antibiotics and/or sulfonamides during attacks or daily for months or even years and the recent injections of gamma globulin for wrongly assumed infective asthma are unnecessary, costly, and of potential danger. Continued or intermittent corticosteroid therapy is unnecessary when food allergies are controlled.

In 50 children, 30 adults, and 15 older persons, relief was achieved without use of antigens, vaccines, corticosteroids, or ACTH. A larger number of such cases could have been reported had we not been tempted to inject inhalants and vaccines needlessly in cases we now realize were due to food allergy alone. Food allergy associated with inhalant allergy as a minor or major cause is also too often unrecognized. Bronchial asthma due to inhalants alone is frequent.

Recognition of the classic history of bronchial asthma due to food allergy and its control in children, adults, and in older persons has depended on our initial use of the cereal-free elimination diet which assumes allergy to cereal grains, as well as to milk, egg, and other less common allergenic foods. Strict adherence to this diet and maintenance of protein requirements and weight are necessary. The decrease or entire suppression of food allergy in the summer with exaggeration in the fall, winter, and early spring frequently allows a liberal diet in the summer compared with a strict elimination diet in the winter. Tolerance for foods may arise in one to four years, or such a diet in the winter may be required for many years.

The control of bronchial asthma with corticosteroids, ACTH, and other new and old drugs without the adequate and persistent study of allergenic causes and especially of the usually neglected food allergy is unscientific. It unfortunately ignores the responsibility of the profession to recognize and control atopic allergy which is causative in practically every patient.

HEART DISEASE SCREENING IN ELEMENTARY SCHOOL CHILDREN

William Morton, M.D., Margaret E.N. Beaver, M.D., Grand Junction, Colo.
and
Richard C. Arnold, M.D., M.P.H., Washington, D.C.

A screening program for the purpose of estimating the prevalence rates for congenital and rheumatic heart disease was carried out among 6,311 children between the ages of 6 and 11 years. Among 165 children thus identified as requiring further study, a secondary program of examinations was carried out. The abnormalities discovered included 33 cases of congenital and 7 of rheumatic heart disease. The study revealed 29 cases of previously unrecognized cardiac abnormality but also relieved at least 15 children of a false diagnosis of heart disease. It was valuable not only in assuring some children of needed treatment but also in determining the diagnostic value of various physical findings.

Pediatric heart disease, in contrast to adult heart disease, is almost invariably associated with chamber enlargement or signs of abnormal cardiac function which enable the abnormal condition to be discovered if sought. Heart disease screening programs are a productive enterprise when conducted among children in a thorough fashion and directed toward detection of the congenital and rheumatic heart defects which are prevalent to varying degrees in various age groups. For instance, congenital heart disease is more prevalent among younger children than among adolescents for the reason that most children with severe defects die before adolescence is reached, although this is counteracted somewhat by the fact that certain of the acyanotic left-to-right shunts (in particular, atrial septal defect) are often not possible to diagnose until the age of 8 to 10 years or even until adolescence. Rheumatic heart disease usually does not appear until 7 to 10 years and is increasingly more prevalent thereafter with advancing age. Thus, there is a difference in the prevalence rates of rheumatic heart disease between populations of younger and older children. The over-all prevalence rate for organic heart disease in children of all ages should be roughly the same, with perhaps a slightly increased rate in adolescents as compared with preschool-aged and elementary school children.

This report is the first of three which will deal with different facets of the entire problem of mass screening for heart disease in children. This paper deals primarily with the results of a screening program in one community and its environs. Prevalence rates of heart disease and innocent murmurs are given, with a discussion of types of disease found, problems encountered, and suggested improvements. The second paper appears on page 1169 of this issue and deals with a comparison of three methods of primary mass screening for heart disease used in two communities. Specificity, sensitivity, efficiency, definitions, and performances are discussed. The third paper [1] compares methods and results of screening programs in two western Colorado communities (different populations than in the second paper), and these results, in turn, are compared with those of previous screening programs by others.

Method

The screening program to be described was conducted in Mesa County in western Colorado. The county has a population of about 35,000 to 40,000 persons, of whom about half live in Grand Junction, which is at an elevation of 4,575 ft. above sea level. There is an active, well-staffed county health department and a conscientious, alert medical society. The screening program was coordinated by a physician from the Colorado State Department of Public Health and financed by the Colorado Heart Association.

As many as possible of the accessible elementary school children in the county received a physical examination limited to inspection of the jugular venous pulsations in the neck, palpation of the radial and femoral pulses, inspection and palpation of the chest, auscultation of the heart with the subject in several positions, and blood pressure recordings from the arms and legs if indicated. This comprised the primary screening procedure and was performed by a total of 13 physicians who were experienced in pediatric cardiac auscultation and who worked in teams to facilitate frequent consultations. In addition, lead V_3R electrocardiographic tracings [2] and 70-mm. chest x-rays were obtained from about two-thirds of the children. Three portable electrocardiographs and the state mobile x-ray unit were used for these procedures.

With the Heart Disease Control Program, U. S. Public Health Service, assigned to the Colorado Sta [illegible] Health (Dr. Morton); Director, Mesa County [illegible] Public Health (Dr. Beaver); and Chief, Hear [illegible] U. S. Public Health Service (Dr. Arnold). Dr. Morton is now a resident in medicine at San Mateo County Community Hospital, San Mateo, Calif.

The primary screening phase of the program took place in the Mesa County schools on school days only; it lasted three weeks and covered 6,311 children, most of whom were in the first six grades. All nursing services and organization of volunteers from the Parent-Teacher Association were provided by the Mesa County Health Department. Twenty-seven schools were covered at 12 separate examining stations, in which children from outlying or smaller schools were brought by bus to the larger and more centrally located schools.

Table 1.—*Age and Sex Distribution of All Children Screened for Heart Disease in Mesa County, Colorado*

	Age, Yr.										
	5	6	7	8	9	10	11	12	13	14+	Total

Total	68	870	989	1,056	1,004	1,053	970	246	46	9	6,311

A secondary screening procedure was also carried out in which all children who were thought to have heart disease or to need further evaluation to rule out the presence of heart disease were reexamined by an experienced pediatric cardiologist who was able to utilize complete history, physical examination, electrocardiogram, full-size chest x-ray, and fluoroscopy. Suspicion aroused by results of any of the three screening methods was enough to insure reexamination. This phase of the program required five full days to reexamine 165 children and was followed by letters describing the findings which were sent to the respective personal physicians (M.D.'s and otherwise) in the community.

Results

Of a total population of 6,604 children who were in the first six grades at this time (including two kindergarten classes and a class for retarded children), 6,311 (95.6%) were subjected to a physical examination. There is no information available to characterize the 294 children not examined.

Table 1 reveals a fairly even age and sex distribution for children aged 6 to 11 years, indicating a representative population for these ages. A total of 33 cases of congenital heart disease and 7 of rheumatic heart disease, in addition to several other types of abnormalities, was discovered. Table 2 presents this information in tabular form.

The 33 cases of congenital heart disease included 7 of atrial septal defect, 6 of pulmonary stenosis, 4 of ventricular septal defect, 4 of aortic stenosis, 3 of patent ductus arteriosus, 2 of coarctation of the aorta, and 1 of atrial septal defect combined with pulmonary stenosis. In addition, there was one child with unmistakable arachnodactyly (Marfan's syndrome) who had no detectable heart lesion as yet, one with dextrocardia (with situs inversus), and four with definite congenital heart disease, type undetermined pending cardiac catheterization. In three children a right-sided aortic arch was associated with the primary defect; one had aortic stenosis, one had atrial septal defect, and the other had dextrocardia. The seven children with rheumatic heart disease included five in whom only the mitral valve was involved, one with only the aortic valve involved, and one with both mitral and aortic valves involved.

The child with "other heart disease" was a boy with a long history of severe asthma who was diagnosed as having cor pulmonale on the basis of electrocardiographic evidence of right ventricular hypertrophy. The cor pulmonale could well be reversible and may disappear, since the asthma had no longer been acute during the past year and a half. The three children with electrocardiographic abnormality included one with isolated complete right bundle-branch block (without evidence of right ventricular hypertrophy) and two with anomalous muscle bundle between atrium and ventricle (Wolff-Parkinson-White Syndrome).

In addition, there were 50 instances of positive past history of acute rheumatic fever. These 50 cases must not be regarded as any basis for prevalence estimates, since this information was gathered as best it could be from several sources and there is no way of checking the reliability of a history of rheumatic fever.

A certain percentage of these cases of heart disease discovered were already known by virtue of the recently established Mesa County Heart Disease Registry. This registry is kept in the Mesa County Health Department and designed to insure follow-up of those patients supposed to be on a prophylactic regimen against recurrent attacks of rheumatic fever. Another group of cases of heart disease found during the screening program were already known to the children's physicians. However, the majority of the cases of heart disease discovered during the screening program were previously unknown. This information is presented in table 3.

The registry actually is much more adequate than table 3 would indicate. It contained the names of 22 of the 50 children listed as having had rheumatic fever. This incomplete coverage is partly a result of the short time that the registry had been established and partly a result of the reluctance of physicians to fill out report forms. It should be mentioned that three of the children with known congenital heart disease had already had corrective surgery.

The primary reason for collecting figures and recording data was to obtain as good a basis as possible for the estimation of prevalence rates for congenital and rheumatic heart disease in this age group. To have completely reliable figures, one would need a population group large enough to provide at least 50 cases of congenital heart disease and 50 of rheumatic heart disease. Unfortunately, the population being reported is apparently not large enough. However, it is believed the figures obtained should be reported with the caution that larger population studies may report different figures which might be more reliable.

TABLE 3.—*Comparison of Diagnoses with Previous Knowledge of Heart Disease*

		Mesa County Registry			Other Knowledge, No.		
		Listed, No.					
Heart Disease	Total	Correct Diagnosis	Incorrect Diagnosis	Not Listed, No.	Correct Diagnosis	Incorrect Diagnosis	Not Known, No.
Congenital	33	1	0	32	6	5	21
Rheumatic	7	1	0	6	2	0	4
Other	1	0	0	1	0	0	1
ECG abnormality	3	0	0	3	0	0	3
Total	44	2	0	42	8	5	29

The prevalence rate of a condition is defined as the number of cases of that condition known to exist in a given population at any one time. For this particular prevalence ratio, the numerator will be composed only of the 40 cases of congenital and rheumatic heart disease. The electrocardiographic abnormalities are not included, since they do not constitute organic heart defects. The case of cor pulmonale is not included because it is probably a transient condition. In the choice of a denominator for the prevalence estimate, one could use the total population at risk (6,604) and compute a minimum prevalence rate, or one could use only the population examined (6,311) and compute a maximum prevalence rate. Both sets of prevalence rates are presented in tabular form in table 4.

TABLE 4.—*Prevalence Rates, in Percentage, of Organic Heart Disease in Elementary School Children*

Heart Disease	Total Population at Risk (6,604)	Examined Population (6,311)
Organic	0.61	0.63
Congenital	0.50	0.52
Rheumatic	0.11	0.11

It may seem to be excessive detail to present both sets of prevalence figures when they are obviously so close, but prevalence estimates have been made from studies based on examinations of a much smaller percentage of the total population at risk. In such instances the two sets of figures represent two ways of regarding the results; they can be further apart; and the difference becomes more significant. The possible significance of the over-all prevalence rate and the rates for rheumatic and congenital heart disease will be discussed in a later paper.

Functional or innocent heart murmurs in children are a fascinating topic, and there is no completely satisfactory explanation for most of them.[3] As with prevalence rates of heart disease, different studies have shown different percentages of the population with an innocent heart murmur. It is probable that most of the differences of opinion about this problem are due to different definitions of terms and to different levels of significance ascribed to what was heard. For the Mesa County program, it was considered advisable to keep a record of all the murmurs heard and their locations. This information is presented in table 5 for all the children without heart disease.

Grade 1 murmurs are included in the records, although no effort was made to keep track of the loudness of the murmurs because of differences in standards and terminology among the examining physicians. Occasional innocent murmurs were as loud as grade 3 on a 6-grade scale. "Venous hums" were included in the group of murmurs heard at the base of the heart. The subdivision of the locations of innocent heart murmurs shown in table 5 was unsatisfactory, since it was noted during the screening program to be not adequately subdivided as to locations and, in some, for sound quality. Perhaps a mimeographed diagram of the precordium should have been included on the record card. This would have permitted more exact differentiation of the location of the innocent murmurs and would have been worth the effort.

A facet of the innocent heart murmur that could stand further clarification is the quality of the sound. "Vibratory" is the term most commonly accepted in the Rocky Mountain area[4] to describe the sound quality of the classic innocent murmur; this denotes a relatively pure sound accompanied by harmonious overtones. However, these murmurs are often composed of disharmonious overtones, and all are not "vibratory" in quality. Some have a definite blowing quality, others are slightly rough, and others are squeaky. This is really a problem in semantics. Although the pitch of the innocent murmur is usually described as low, this is a characteristic of the innocent murmur that often is not too closely attended. To those of us without a phonocardiogram, pitch may most readily be determined by the relative difference between the sound as heard through the diaphragm of the stethoscope (high-pitched sounds are heard relatively better) and the sound as heard through the bell of the stethoscope (low-pitched sounds are heard relatively better). Although probably many functional heart murmurs are indeed low-pitched, many must be called medium-pitched.

TABLE 5.—*Comparison of Age and Sex with Innocent Heart Murmurs and Their Locations*

		Murmurs,* No.

Both sexes		4,201	379	1,125	104	294	116	2,068	6,269

* L.S.B. = left sternal border; W.P. = whole precordium.

The great hallmark of the innocent heart murmur is its variability with respiratory and positional changes. The murmur may completely disappear during a moderately deep, held inspiration, while "organic" murmurs do not. The murmur may be audible when the subject is in the recumbent position and not when he is in the erect position or, rarely, vice versa. The point where the murmur is heard loudest often shifts considerably when the subject's position changes. Exertion may accentuate or diminish the murmur. Anxiety mimics the effects of exertion, especially in children.

Table 5 shows that there are more boys than girls with functional heart murmur. There were also more boys screened than girls. However, among the children 10 and 11 years old, more girls than boys had murmurs. It is doubtful that the totals of each sex in each age group are large enough to be conclusive in this regard. The over-all percentage of innocent heart murmurs heard in normal children in this study (33%) agrees well with percentages found in previous similar studies on Colorado children: 30% of 1,617 elementary school children[2] and 36% of 11,236 sixth graders.[5] This fact would suggest a certain degree of comparability with the previous studies.

No effort was made to obtain statistics on variations in heart sounds heard during the screening program. In particular, the respiratory variation in the splitting of the second heart sound as heard in the second left intercostal space was a closely attended phenomenon during each auscultation. Especially in children, the second heart sound in the "pulmonary area" usually is split during inspiration and single or less widely split during expiration.[6] During this and previous screening activities, it was noted that this split varied in normal children from being only occasionally heard during inspirations to a practically constant wide splitting during expirations. Of course, the loudness of the second sound is of considerable assistance in judging the normality of the respiratory splitting which is significant, since pulmonary hypertension will usually cause a loud and often snapping second heart sound with loss of the respiratory variations in splitting and a fixed reduplication. In addition, a constantly pure second sound in the pulmonary area may be a feature of pulmonary or aortic stenosis, although this has been reported to be an inconstant phenomenon.[7] Inspiratory splitting of the first heart sound along the lower left sternal border and at the apex was another event that could have been recorded. Perhaps another similar study could shed more light on the normal variations and occurrence of heart sounds as well as heart murmurs. This problem is of particular interest because heart sounds are often of more value in identification of heart disease than heart murmurs. Indeed, heart murmurs are usually judged by the accompanying sounds.

It is interesting to note what was advised as to recommendations for the children who were reexamined. This is shown in table 6. The recommendations were made with primary attention to which course of action would be the most practical in a community 260 miles away from where cardiac catheterization could be done. In addition, two of the children with congenital defects were being followed for serious primary mental deficiencies as well, and it was considered that expensive corrective procedures were best deferred in these instances.

Comment

Most physicians work with patients who come or are brought to them with a complaint. In the field of pediatric heart disease this means that, by the time the physician sees the patient, the patient usually has fairly characteristic signs of illness from which a diagnosis may be extracted. As might be expected, a screening program will tend to discover patients in an earlier stage of the progression of their condition. This means that often the diagnostic signs will be more equivocal in the patient with previously unknown heart disease than at a later date when symptoms might have caused him to seek a physician's care. This phenomenon is especially apparent in congenital heart disease wherein there are wide variations in the rate of progression of the condition and its complications, depending on the extent of the defect and on unknown factors in the constitution of the patient. In this study, as in a previous one,[2] relatively mild degrees of congenital defects without functional impairment, such as localized ventricular septal defect (Roger's disease) or some cases of atrial septal defect, pulmonary stenosis, and aortic stenosis, are included as definite congenital heart disease because knowledge at present cannot definitely rule out the possibility that these persons may some day have disability as a result of their defect. This is also the line of reasoning responsible for classifying the case of arachnodactyly as congenital heart disease, even though there is as yet no demonstrable defect. In congenital heart lesions, it is particularly important to discover defects (especially shunts) before irreversible pulmonary hypertension has set in, so that life will actually be prolonged by corrective surgery.

The case of one 7-year-old girl, included in the "normal" category in table 2, may illustrate a phenomenon recently described by Silber,[8] who mentions that viral carditis may produce transient murmurs identical with those of rheumatic heart disease. At the time of the primary screening examination, the girl had had a low-grade fever and wet cough, that had been present for about two weeks, some lassitude, and a grade 3, blowing, high-pitched pansystolic murmur heard all over the precordium, loudest at the apex, radiating to the left axilla, and accompanied by a muffled first heart sound in the "mitral area." Intermittent rhonchi were heard over both lung fields. There was no other history of any other manifestations of rheumatic fever, her sedimentation rate was normal, and her family history was negative. Although this does not rule out the supposed entity of subclinical rheumatic fever, there was no acute episode of rheumatic fever to account for the very definite and previously unheard murmur of mitral insufficiency. Four weeks later, when she was reexamined by the pediatric cardiologist in conjunction with the screening physician, it was readily agreed that the patient had a grade 2, vibratory, low-pitched systolic murmur heard all over the precordium, loudest in the fourth left intercostal space, and not heard in the left axilla. At this time the first heart sound was entirely normal, there was no indication of upper or lower respiratory tract infection, and the heart murmur was judged to be classically innocent. In the interval between the examinations, the patient had been receiving orally one penicillin tablet per day, but no anti-inflammatory drugs, and she had not been kept home from school. Of course the possibility of an endocarditis has not been ruled out, although this is a little remote considering the

clinical course. Since a virus or its antibody response was not definitely identified, the case is open to speculation, but the hypothesis of transient viral carditis is interesting and thought-provoking.

The physicians of this Colorado town are, as a group, probably as well-trained and able to diagnose heart disease as any other comparable group in the United States. Thus, the fact that 29 of these 43 cases of heart abnormalities were previously unrecognized is no reflection on the local medical practice. As previously mentioned, most of those children were not having the symptoms or signs of illness that would cause their parents to seek medical attention. In addition, many of the incorrect previous diagnoses mentioned in table 3 had been made by paramedical personnel in the community (who seem interested in heart disease but not as well trained in the subject).

One discouraging facet of this sort of program is that not all the subjects in whom heart disease is discovered will receive the recommended diagnostic studies or corrective operation. In fact, from past experience gleaned from other similar surveys, probably only about one-half of those who have not already had an operation and in whom disease was discovered in this survey will actually receive the benefit of the available therapeutic potential in time to really prolong life to somewhere around the normal expectation. There are many reasons for this, most of them sociological: parental maladjustments, distrust of doctors, financial embarrassment, refusal to accept the free care available, and other factors. Cases of acyanotic congenital heart disease are particularly apt to result this way because the children "don't look sick" to the parents. By the time they do look sick enough, it is often too late in the progression of the disease to obtain a cure by operation; either the patient is too poor a surgical risk, or irreversible pulmonary vascular changes have occurred. This sort of thing is probably more apt to happen in a rural then an urban population.

It is as important to avoid overdiagnosis as underdiagnosis. The production of excessive anxiety concerning the heart should be avoided if possible. That considerable anxiety is generated in the children by such a screening procedure is apparent when one discovers later from teachers and parents what comments the children have made and to what lengths they sometimes go to avoid the screening procedure.

It can be readily seen that the discovery of previously unknown cases of heart disease is a significant event. Children with rheumatic heart disease may be placed on a prophylactic regimen against recurrent attacks of rheumatic fever, and children with congenital heart disease may undergo corrective operation or may be given follow-up examinations until such time as the development of symptoms or signs of dysfunction might make operation desirable. However, the other side of the coin is that there were at least 15 children who were relieved of a false diagnosis of heart disease. This is a minimum figure, since this result was not anticipated and the records kept did not include previous diagnoses on all the normal children. These children were usually on rather severely restricted activity regimens and in some cases were real behavior problems in school and at home, utilizing their supposed heart defect to immunize themselves against punishment. However, it is possible that some of these children received their diagnosis during an episode of illness similar in effect to the one described in the 7-year-old girl with an upper respiratory infection. The possibilities for error make it necessary to examine a child at least twice before making a definite diagnosis of heart disease.

Summary

In a screening program for heart disease in elementary school children, 33 cases of congenital heart disease and 7 of rheumatic heart disease were discovered in a total population of 6,604 children, 95.6% of whom were examined. Other types of heart abnormality were also found. Of the children without heart disease, 33% had innocent heart murmurs.

222 39th Ave., San Mateo, Calif. (Dr. Morton).

This study was supported by a grant from the Colorado Heart Association. Examining physicians were provided by the Heart Disease Control Program of the U. S. Public Health Service, the National Jewish Hospital, Denver, and the University of Colorado Medical Center. Nurses and auxiliary personnel were provided by the Mesa County (Colorado) Department of Public Health. Record analysis and guidance were provided by the Colorado State Department of Public Health.

COMPARISON OF THREE METHODS OF SCREENING FOR PEDIATRIC HEART DISEASE

William Morton, M.D., Murray S. Hoffman, M.D., Roy L. Cleere, M.D., M.P.H.
and
Horace J. Dodge, M.D., M.P.H., Denver

Three screening methods were compared as to specificity and sensitiveness in the detection of cardiac abnormalities by applying them to each of 5,654 children. The three methods consisted of a single-lead (V_3R) electrocardiogram, a miniature chest roentgenogram, and a limited physical examination. For each method it was possible to define a sensitivity index, a specificity index, and their product, an efficiency index. The V_3R gave a specificity index of 0.190 (ratio of true positive to total positive findings), and of 58 children with abnormal V_3R tracings 44 had normal hearts. The physical examination, used singly, was the most specific and the most sensitive and gave the highest efficiency index, but none of the methods was infallible.

Screening methods for the purpose of detecting heart disease have received extensive evaluation in adults. Screening programs with use of chest x-ray, brief history, limited physical examination, blood pressure recordings, and electrocardiogram singly or in combination have been described.[1] In adults, rheumatic heart disease and hypertensive heart disease are more readily discovered by screening, but arteriosclerotic heart disease (the major problem) is considerably more difficult to detect on a screening basis unless angina pectoris is present or a myocardial infarction has occurred, and even then detection of disease is not easy. It has also been the experience in previous studies that incipient or even frank cor pulmonale in adults is difficult to detect on a screening basis.

However, in children, the problem of screening for heart disease is made easier by the fact that the two commonest types of heart disease, congenital and rheumatic, generally produce specific chamber enlargement, pulmonary vascular changes, or characteristic heart murmurs which produce definite auscultatory electrocardiographic, or radiologic signs.

Increased consciousness of heart disease on the part of the general public, the development of corrective surgery for various types of heart disease, and the development of effective prophylaxis against recurrent attacks of rheumatic fever have made the discovery of heart disease among children a valid community public health activity. This is especially true since most physicians have neither the time nor the desire (and often not the experience) to screen hundreds and sometimes thousands of children to weed out the approximately 0.5 to 1.0% of children who have heart disease and who will benefit from medical attention.

There is a need for more information regarding the sensitivity, specificity, and reliability of the various methods which might be used singly or in combination in screening for pediatric heart disease. Estimates of these must be based on studies of large populations of children in which all have been checked by the best other method in addition to the one being tested. For purposes of statistical validity, it is estimated that the population should be large enough to yield at least 50 cases of heart disease, which would mean that at least 5,000 to 10,000 children should be screened to test any given method.

The only real practical check available to evaluate the various screening methods is the total evaluation, including history, careful physical examination by physicians experienced in cardiac diagnosis, electrocardiogram, x-ray, and, at times, selected physiological tests. It becomes apparent that the problem of evaluation of a single diagnostic test is a difficult process. The primary purpose of this paper is to present the information obtained from three screening methods used simultaneously on the same group of grade school children.

Method

Over a period of two school years in two western Colorado communities, a total of 5,654 grade school children were examined by single-lead electrocardiogram, miniature chest x-ray, and limited physical examination. A total of 7,928 children were examined by at least one method, but only 5,654 were subjected to all three screening methods. The prevalence rates noted for heart disease and innocent

With the Heart Disease Control Program, U. S. Public Health Service, assigned to the Colorado State Department of Public Health (Dr. Morton); Chief of Cardiology, National Jewish Hospital (Dr. Hoffman); Executive Director, Colorado State Department of Public Health (Dr. Cleere); and acting head of the Department of Preventive Medicine, University of Colorado Medical Center (Dr. Dodge). Dr. Morton is now a resident in medicine at San Mateo County Community Hospital, San Mateo, Calif. Dr. Dodge is now Professor of Epidemiology, University of Michigan School of Public Health, Ann Arbor, Mich.

heart murmurs have been reported elsewhere,[2] and this report will concentrate on the comparison of sensitivity and specificity of the three methods used.

The primary physical examination was performed by selected physicians experienced in cardiac diagnosis; it consisted of inspection of the jugular venous pulses, palpation of the radial and femoral arterial pulses, inspection and palpation of the chest, and auscultation of the heart with the child in several positions and with attention to respiratory variations in heart sounds. Blood pressure recordings from arms and legs were obtained when indicated by heart sounds or arterial pulse characteristics.

TABLE 1.—*Comparison of Processing Rates for Three Screening Methods for Heart Disease*

Primary Screening Test	Personnel Required	Children Examined per School Day, No.	Results Read per Hr., No.
Physical examination (1 team of 2 M.D.'s)	2 physicians, 1 nurse, 2 PTA mothers	300-400	Immediate
ECG, V_3R lead (1 machine)	1 trained nurse or technician, 2 PTA mothers	200-300	500-600
70-mm. chest x-ray (mobile unit)	2 technicians and 2 PTA mothers or 1 technician and 3 PTA mothers	500-600	400-500

The single V_3R lead of the electrocardiogram was used as a screening tool because a large proportion of the congenital heart defects found in this age group are conditions associated with right ventricular hypertrophy, most readily detected by right precordial leads. Two criteria for this abnormality were used: (1) ratio of R wave to S wave greater than unity and (2) ventricular activation time (from onset of QRS complex to peak of tallest R wave) of 0.04 seconds or longer. If both criteria were present, the tracing was considered abnormal. If only one criterion was present, the finding was considered borderline. The tracings were obtained by registered nurses who were trained for this task, and they were assisted by mothers from the Parent-Teacher Association. Alcohol sponges were used in place of electrode paste to save time.

The state mobile x-ray unit, ordinarily devoted to screening for tuberculosis, was used to obtain 70-mm. chest x-rays. The x-rays obtained in the heart disease screening program were also examined for tuberculosis, and as a result 10 children were suspected of having the latter disease. Children were noted by the technicians to require more effort to x-ray than adults, and the smallest children stood on various sized boxes in order to reach the screen. Since the screening procedures were organized to be performed in rapid succession on the same children, it was necessary to know the rate at which children could be processed. Table 1 presents the maximum performance rates for the three methods. The PTA mothers listed under personnel are used for dressing and undressing children, keeping noise down to a reasonable level, seeing that no children are overlooked, and similar needs. Usually the children are brought to the examining site by class, and the teachers are also present.

Actual organization of screening schedules and auxiliary personnel was done by the public health and school nurses from the local health departments. One or two nurses were always present during the screening procedure. The entire program was coordinated by the Heart Disease Control Program of the Colorado State Department of Public Health and financed by the Colorado Heart Association. Screening physicians were provided largely from Denver, although there was some participation by interested physicians in each community.

As a result of the primary screening phase of the program, any child screened out by any of the three methods was reexamined by a pediatric cardiologist who utilized complete history, physical examination, electrocardiogram, full-size chest x-rays, fluoroscopy, and, at times, such physiological procedure as heart catheterization. The parents were told of the findings on the spot, and, in addition, letters were mailed to family physicians describing the findings, the probable diagnosis, and any further recommendations.

Results

Table 2 shows the age and sex distribution of the children screened for heart disease by all three methods. From this table, it may be seen that a representative population (with respect to age and sex distribution) of grade school children was screened.

Accumulating the results of all three screening methods, this population of 5,654 children included 36 with congenital heart disease, 5 with rheumatic heart disease, 1 with "other" heart disease (cor pulmonale), and three with electrocardiographic abnormality without organic heart disease; 5,609 children were normal.

Since the V_3R lead was used to detect right ventricular hypertrophy only, the children were divided into those with this condition and all others. The child with "other" heart disease happened to have right ventricular hypertrophy. The three cases of electrocardiographic abnormality without organic heart disease consisted of two of anomalous muscle bundle between atrium and ventricle (Wolff-Parkinson-White syndrome) and one of isolated, complete, right bundle-branch block. The children with rheumatic heart disease all had mitral valve involvement only. The cases of congenital heart disease

TABLE 2.—*Comparison of Age and Sex of Children Screened for Heart Disease*

	Age, Yr.									
Sex	5	6	7	8	9	10	11	12	13+	Total
Male, no. ...	2	468	477	465	498	455	403	110	16	2,894
Female, no. .	4	438	477	481	455	417	384	90	14	2,760
Total	6	906	954	946	953	872	787	200	30	5,654

consisted of 10 of atrial septal defect, 5 of ventricular septal defect, 5 of aortic stenosis, 5 of pulmonary stenosis, 3 of patent ductus arteriosus, 2 of coarctation of the aorta, 1 of arachnodactyly (Marfan's syndrome), 1 of dextrocardia, 1 of tetralogy of Fallot, and 3 of congenital heart disease, type unknown.

When considering the number of different screening methods, it is helpful to consider the specificity of the tests for a condition and the sensitivity of the tests in detecting the condition. These terms give a numerical measure of the tests. Thus, the following definitions of terms are in order: 1. Specificity. A test is wholly specific when the result is positive only in the presence of the condition for which the test is made. The measure of specificity is the ratio of true positive tests to total positive tests. 2. Sensitivity. A test is wholly sensitive when the result is invariably positive in the presence of the condition for which the test is made. The measure of sensitivity is the ratio of true positive tests to the total number of patients having the condition for which the test is made. 3. Efficiency. In order to have some expression which will combine specificity and sensitivity, an index of efficiency is calculated by multiplying the ratios of specificity and sensitivity.

A screening test with a relatively high sensitivity may have a relatively low specificity and vice versa. By inspection of table 3, it will be seen that all the screening methods missed cases of heart disease (false-negative results) and all gave a certain proportion of false-positive results. It is helpful to assemble these figures in another table (table 4) for comparison.

Table 3.—*Comparison of Diagnostic Categories with Results of Three Methods of Screening for Heart Disease*

		Results, No.						
		Physical Examination		ECG, V₃R Lead			Chest X-ray, 70 Mm.	
Diagnosis	Total	Positive	Negative	Abnormal	Borderline	Normal	Positive	Negative
Congenital heart disease								
Right ventricular hypertrophy	13	10	3	11	1	1	7	6
Other	23	20	3	0	5	18	5	18
Rheumatic heart disease	5	5	0	0	0	5	3	2
Other heart disease (cor pulmonale)	1	0	1	0	1	0	0	1
ECG abnormality	3	0	3	3	0	0	0	3
Normal	5,609	72	5,537	44	437	5,128	41	5,568
Total	5,654	107	5,547	58	444	5,152	56	5,598

It is interesting to note that seven cases of heart disease would have been missed by use of the physical examination alone. In judging the V_3R lead, only the "abnormal" category was considered as positive in computing the specificity, and only the cases of right ventricular hypertrophy were considered in computing the sensitivity. As has probably been noticed, table 4 was computed on the assumption that the screening program discovered all the cases of heart disease within the population of 5,654 children. This is only an assumption, because cases could have been missed even with the simultaneous use of three screening tests. The only way to gain a more reliable foundation for this sort of work would be to examine every one of a population of several thousand children at a diagnostic center where they would receive a complete diagnostic study, including fluoroscopy.

Table 4.—*Comparison of Specificity, Sensitivity, and Efficiency of Three Screening Methods, Used Alone and in Combination*

	Specificity†		Sensitivity‡		
Method*	Ratio	Quotient	Ratio	Quotient	Index of Efficiency§
Physical examination	35:107	0.327	35:42	0.833	0.272
ECG, V₃R lead	11:58	0.190	11:14	0.786	0.149
Chest x-ray, 70 mm.	15:56	0.268	15:42	0.357	0.096
Physical examination plus ECG	37:150	0.247	37:42	0.881	0.218
Physical examination plus x-ray	37:152	0.243	37:42	0.881	0.214
Chest x-ray plus ECG	20:107	0.187	20:42	0.476	0.093

* All methods except that with ECG alone (for right ventricular hypertrophy) computed for all heart disease.

† Ratio of true positive tests to total positive tests.

‡ Ratio of true positive tests to total number of subjects with condition for which test is done.

§ Ratios for specificity and sensitivity multiplied.

Of the three screening methods used singly, the physical examination was the most specific, although all methods were fairly close in this respect and produced many false-positive results. The V_3R lead was the least specific, even though it was only judged in the detection of right ventricular hypertrophy. The physical examination was also the most sensitive, with the V_3R lead a close second (only in the detection of right ventricular hypertrophy) and the 70-mm. chest x-ray a poor third. Thus, the physical examination seemed to be the most efficient screening method.

Inspection of the tabular comparison between the various combinations of screening methods (table 4) shows that, although use of the physical examination in conjunction with either the V_3R lead or the 70-mm. chest x-ray will increase the sensitivity of the screening program, the specificity would then fall below the value obtained when only the physical examination is used as a screening method. Of course, the combination of all three screening methods used simultaneously is even more sensitive but less specific than the physical examination used alone. However, there is nothing against which to measure the over-all sensitivity of the entire screening program in this study.

Comment

It must be remembered that these screening programs were conducted afresh in each community and that, if this program were set up on a continuing basis with the community physicians gaining experience in screening for heart disease each year, the values presented for specificity, sensitivity, and efficiency of the screening program should rise. Also, it would certainly be much more advantageous in respect to time and finances to screen for heart disease with use of only one screening method instead of three. At the most, two methods might be used simultaneously.

The V_3R lead was fairly sensitive in the detection of right ventricular hypertrophy, and considerable moral support was given to the screening physicians when the tracing was taken just before the physical examination and attached to the child's record card. It must be pointed out that the electrocardiographic criteria used herein for the diagnosis of right ventricular hypertrophy were limited by the technique, in that such patterns as deep S waves in the left precordial leads or shift in precordial transitional zone to the left could not be used to make this diagnosis. Had complete electrocardiographic tracings been obtained on each of these children and read for right ventricular hypertrophy, the screening method would probably have been more sensitive but would have lost a good deal of specificity. It should be emphasized that, of the 58 children with abnormal V_3R tracings, as judged by rather strict standards, only 11 had right ventricular hypertrophy, 3 had electrocardiographic abnormalities, and 44 had normal hearts. The 44 normal children with electrocardiographic evidence of right ventricular hypertrophy should cause one to reflect that the electrocardiogram is an ancillary and not a primary diagnostic tool. However, it would seem to be an advantage to have electrocardiographic assistance in the diagnosis of conditions which might cause left ventricular hypertrophy or combined ventricular hypertrophy. A complete electrocardiogram would probably complicate the record handling and interpretation procedures too much to be of that much additional value. However, since the child is already "wired" for a chest lead, perhaps one or maybe two additional leads could be recorded and judged by definite criteria without loss of the relative simplicity of the procedure.

The chest x-ray is not a sensitive tool with which to detect heart disease, especially in children, most of whom are in an early stage of their disease. It is certainly an excellent means, however, of following changes in heart size and configuration and in pulmonary vascularity in patients whose heart disease is already known. X-rays are also invaluable in making a diagnosis of heart disease. The screening efficiency of the x-ray was decreased by the fact that there is a wide range of normal appearance of the heart contour. This, coupled with the fact that many of the subjects screened had no gross cardiac enlargement, made the method less desirable for this purpose in this age group. In view of the cost and size of x-ray equipment, the chest x-ray probably does not have as much developmental potential as a mass screening tool as other methods.

This study, with simultaneous use of three screening procedures, has established one fact: no screening method is infallible. Even in the physical examination, when performed by experts, heart disease can be overlooked in an age group in which it has previously been thought that heart disease should not be missed. This has a bearing on past studies of prevalence rates of heart disease in this age group, which have usually been based on the physical examination. It means that, if the studies were performed on large enough groups of children (over 5,000), the prevalence rates offered probably erred on the low side of the true prevalence rates.

Recently, several investigators have been developing the phonocardiogram with heart sound recordings on hi-fi tape as a mass screening tool for discovering heart disease among children. The phonocardiogram operated by a technician would save physicians' time and make possible the screening of a large number of children with minimum expense. It must be remembered that the phonocardiogram as used in this fashion would be an ancillary tool, as are the electrocardiogram and the chest x-ray, and it should not be expected to measure up to the results of a screening program with trained physicians who use their hands and eyes in addition to their ears. This is merely to caution against overenthusiasm for a new tool and not to detract from the many obvious advantages of working with a phonocardiogram in this fashion.

The population of 5,654 children in this study cannot be used in computing prevalence rates of heart disease, since it was arbitrarily selected from a larger group of 7,928 children screened. The group discussed in this paper was selected solely on the basis of having had all three screening procedures performed.

INTRAVENOUS USE OF OXYTOCIN (PITOCIN) FOR INDUCTION OF LABOR

Martin Clyman, M.D., Jean Pakter, M.D., Harold Jacobziner, M.D.
and
Freida Greenstein, B.A., New York

The extent to which oxytocin is being used to initiate or stimulate uterine contractions in labor was investigated by analyzing certain information on birth and fetal death certificates in New York City. Of 165,150 live births in 1955, 7,694 (4.7%) were induced with intravenously given oxytocin. In 1956 the over-all reported incidence rose to 5.0%. Three case-histories are given to illustrate the irrational use of this drug. The data showed that its use was influenced by the season of the year and by the socioeconomic status of the patient and that in cesarean sections and breech deliveries the prior use of oxytocin increased the infant mortality.

Posterior pituitary products, administered intramuscularly, were used in obstetrics for many decades for the induction and/or stimulation of labor. A new modality, oxytocin (Pitocin), diluted for intravenous use, was first suggested for stimulation and induction of labor by Page[1] in 1943. His report was followed in 1949-1950 by the clinical reports of Theobald and others[2] and Hellman[3] on dilute oxytocin in 5% glucose solution (1:5,000 to 1:7,000), given intravenously. These reports initiated the widespread use of oxytocin for the induction and stimulation of labor. An ever-increasing trend in this usage is attested by subsequent reports in the literature.[4]

Many questions, such as the following, need to be raised regarding the possible deleterious effects of intravenously given oxytocin. 1. Does it increase the incidence of ruptured uterus? 2. Does it increase the incidence of premature separation of the placenta? 3. Does it increase uterine hemorrhage? 4. Does it increase the incidence of prematurity? 5. Does it increase perinatal mortality? 6. Is it harmful in a breech presentation? 7. Is the infant unduly traumatized? 8. Does it produce fetal anoxia with resultant central nervous system damage that may not be ascertained until years later?

Published studies[5] on intravenously given oxytocin have been confined to an individual hospital or group of hospitals where careful supervision usually prevails. These sources indicate that with proper control this method does not significantly increase the hazard to mother or infant. In an effort to determine the extent of usage and to obtain additional information about the questions raised, this present study was initiated.

Method of Study

This report is based on an analysis of birth and fetal death certificates from New York City for 1955-1956 (see figure). These certificates request the following information: 1. Was induction attempted? 2. Indication? 3. Method of induction? 4. Successful? ("Successful" is interpreted as the initiation of active labor resulting in birth per vaginam.) These items were coded and punched on I. B. M. cards. The coding was set up as shown in table 1.

For the purpose of this study, all certificates coded 4, 5, or 6, which refer to the induction of labor with oxytocin, were included, and the tabulations were limited to these. If oxytocin was stated to be used for "stimulation of labor," then codes 4, 5, or 6 were not utilized and these cases were not included. Information regarding acceleration (or stimulation) of labor is not available from the birth certificate. Failure to answer one or more of the questions on the birth certificate regarding the use of intravenously given oxytocin is recognized as a limitation in this analysis. Many cases of induction are categorized as resulting from "stimulation," and, therefore, the actual incidence is under-reported. Information and correlations were obtained which are of interest and which may serve to stimulate further clinical studies relating to the use of intravenously given oxytocin.

Additional information was obtained from a questionnaire sent to all the directors of obstetric services of hospitals in New York City. This requested information on live births and fetal deaths occurring on the private and ward services, with regard to the use of intravenously given oxytocin for the stimulation and induction of labor. A response was obtained from 79 hospitals, for 1955, with a total of 128,324 live births. These included 49 voluntary, 16 proprietary, and 14 municipal hospitals. A similar questionnaire was sent for the year 1956, was completed by 83 hospitals, and resulted in information on 136,451 live births.

Results

Frequency of Inductions.—Of 165,150 live births in New York City in 1955, 7,694 (4.7%) were induced with intravenously given oxytocin. In 1956 the over-all reported incidence rose to 5.0%. In 1955, of 103,791 births on the private service, 6,890 (6.6%) were induced with oxytocin; of 58,991 births on ward services, 804 (1.4%) were induced. In 1956 an increase in utilization of oxytocin occurred in both private (7%) and ward services (1.7%). These data would indicate that oxytocin is used approximately five times more frequently on private than on ward services. A variation is noted among private patients, depending on whether they are delivered in voluntary or proprietary hospitals. Oxytocin is used two and one-half times more frequently on the private services of voluntary hospitals than on those of proprietary hospitals.

TABLE 1.—*Coding Methods Used for Data Taken from Birth and Fetal Death Certificates*

Code No.	Indications for Induction of Labor	Method of Induction of Labor
0	Not induced	Not induced
1	Elective	Other than oxytocin, successful
2	Therapeutic (including postmaturity, rupture of membranes, erythroblastosis, Rh—, premature separation of placenta, placenta previa, abruptio placentae, and ablatio placentae)	Other than oxytocin, not successful
3	Dead baby—no fetal heartbeat	Other than oxytocin, success not stated
4	Other (including nephritis, heart disease, diabetes, syphilis, tuberculosis, benign neoplasms, malignant neoplasms, and hypertension)	Posterior pituitary injection (Pituitrin) and/or oxytocin, successful
5	Uterine bleeding	Posterior pituitary injection and/or oxytocin, not successful
6	Toxemia (eclampsia and preeclampsia)	Posterior pituitary injection and/or oxytocin, success not stated
7	Indications not stated	Attempted induction, method not stated
8	Not stated whether induced	Not stated whether induced

Indications for Induction of Labor.—Elective induction constitutes approximately half of all inductions in 1955-1956. Of the 7,694 inductions in 1955, 3,688 were elective; of these, 3,548 (96%) were in private patients (table 2). Of the 6,890 inductions on the private service in 1955, 3,548 (51.5%) were for elective reasons, whereas of 804 on ward services, only 140 (17.4%) were elective. It would appear that on ward services oxytocin is used mainly where a therapeutic indication exists, whereas on private service the indication is chiefly elective. It is of interest that in 1956 an increased trend for elective induction is noted even on the ward services.

Use of Oxytocin by Type of Hospital.—Among the 100 hospitals (excluding two federal hospitals) with maternity services in New York City, three categories exist. They are (1) proprietary hospitals—privately owned and services limited entirely to private patients, (2) municipal hospitals—under the jurisdiction of the department of hospitals and limited to ward patients, and (3) voluntary hospitals—having both ward and private patients in varying proportions, depending on the given hospitals. A wide range in the use of intravenously given oxytocin was observed among the hospitals, in 1955, varying from a high of 29.9% to a low of 0.1% (table 3). In 1956 the hospital previously exhibiting the greatest use of this drug showed an even greater rise—to 54.2%.

Results of Questionnaire.—Oxytocin, for both induction and stimulation of labor, was used in 14.0% of 128,324 live births in 1955; 6.4% of live births were induced with intravenously given oxytocin, and 7.6% of live births occurred after its use for the acceleration of labor (table 4). The data obtained in 1956 showed little change from those of 1955. For both years combined, induction on the private service was recorded for 9.1% of the births as compared with 1.8% for the ward service. Stimulation on the private service was noted in 11.9% of cases as compared with 3.2% on the ward service. Induction was used almost twice as frequently on ward services of voluntary hospitals as on ward services of municipal hospitals. To a lesser degree the same trend is shown for stimulation. Among private patients, induction was used more than two and one-half times as frequently in voluntary hospitals as in proprietary hospitals. Again, to a lesser degree, the same trend is shown for stimulation.

Seasonal Variation.—Analysis of births after induction by oxytocin revealed a pattern of seasonal variation which was in marked contrast to that exhibited by all live births in New York City. Over a period of years no significant variation in number of births has been found to exist for New York City by month (table 5).

In 1955, peak months for births after induction were observed for July, August, and December. Similar peaks occurred (with the addition of June) in 1956. These rates were significantly higher than those prevailing during the remaining months. The rises were primarily a reflection of usage on private services. By contrast, on the ward service, where the indication is chiefly therapeutic, a plateau is noted. Significantly, in the elective group, the monthly peaks coincided with the over-all use on private service. It would appear that there is a relationship between peak periods of usage and vacation months (table 5).

Use of Oxytocin in Relation to Age and Parity of Mother.—In New York City, 34% of all live births are to primiparas and 32% to secundiparas. For live births occurring after oxytocin induction, the highest percentage is observed in the secundipara and next in the primipara. A significant observation was made that in 1956 there was an increased use of oxytocin for induction among mothers with a parity of three or more. The age distribution of the mothers in the group given oxytocin approximates the age distribution of mothers for all live births in New York City.

Total	83	136,451	82,461	53,990	8,134	7,152	982	12,432	10,465	1,967

Conditions Present During Pregnancy.—On the live birth certificates for 1955 the check list indicated at least one or more conditions present during pregnancy in 8% of the cases. In the group of live births where oxytocin was used for induction, one or more conditions were checked in 15%. The higher frequency of "conditions" is as expected, since intravenously given oxytocin is administered for therapeutic as well as elective indications. Preeclampsia and eclampsia were leading conditions noted, with an incidence of 44.5% for both services combined; incidence in private service was 39.3% and in ward service 57.6% (table 6). The higher incidence of preeclampsia and eclampsia on the ward service is not unexpected. Hypertensive disease, heart disease, and neoplasms showed a higher incidence in patients on the private services than on the ward services.

Mode of Delivery.—In patients in whom induction by use of oxytocin was utilized, the percentage of spontaneous deliveries was significantly lower than in those not induced. Conversely, the percentage of forceps deliveries in the induced group was higher for both private and ward services than in those not induced. The higher percentage of forceps deliveries in those induced is to be expected, since oxytocin was used for the purpose of expediting delivery, for either elective or therapeutic reasons (table 7).

The percentage of breech deliveries induced by oxytocin on the private service was lower than that for the noninduced, whereas on the ward service the percentage of breech deliveries in the induced group was not significantly different from that of the noninduced. These differences observed are as anticipated, since in the private service induction is largely done for elective reasons and, therefore, a minimum of breech deliveries would be included.

On the private service, the percentage of cesarean sections in the induced group was much lower than in those not induced. For 1955, the incidence of cesarean section was 2.2% in the induced group as compared with 6.2% for those not so induced. In 1956 a similar relationship is noted (1.9% as compared with 6.1%). This finding also is as expected, since the indication for induction is primarily elective for private patients. By contrast, on the ward service, the percentage of cesarean section is higher in the induced group. This is another reflection of the relatively greater use of oxytocin for therapeutic indications among ward patients.

In 1955-1956, cesarean sections were performed on 372 patients who received oxytocin for induction. Seventy-eight percent of the sections (290) were performed on private patients. In 16.6% (62) of the 372 sections the indication for induction was stated as elective.

In analyzing the data on the group delivered by cesarean section after induction, there were 47 cesarean sections performed for fetal distress. Seven of these patients had received oxytocin on an elective basis. One may draw the inference that fetal distress followed the use of oxytocin, necessitating the section. Of the 98 sections performed for cephalopelvic disproportion, 23 were stated to have been induced electively. These were most likely unrecognized cases of disproportion. In 38 of the 98 cases of cephalopelvic disproportion, it was stated that induction had been used for therapeutic reasons. In these cases it is difficult to reconcile the use of oxytocin in the face of recognized disproportion.

Seven mothers in this group had had previous cesarean sections. This raises the question as to why oxytocin was used at all in this group, since the risk of uterine rupture is acknowledged to be greater in such cases. Eight elderly primiparas (over 35 years of age) were subjected to induction before cesarean section.

Successful Use of Oxytocin.—A definition for successful does not appear in the instructions given for filling out birth certificates. It is understood as meaning the induction of active labor resulting in birth per vaginam. Of the live births induced by use of oxytocin in 1955 and 1956, 80.6% were classified as successful, 2.8% unsuccessful, and 16.6% in neither category.

Among the 441 unsuccessful inductions, 222 (50%), of deliveries were by cesarean section. In this group 54 patients were given a trial of labor with use of oxytocin for a period of three hours or more. Twenty-six of these were in labor more than 12 hours before termination by cesarean section. It appears that a significant number exceeded a trial period of less than three hours. Of these 54 patients subjected to long trial periods of labor, 11 had received oxytocin electively.

Where "successful" was stated, 72 were delivered by cesarean section. This may indicate either an error in filling out the certificate or a misinterpretation of the term successful on the part of the doctor filling out the certificate (tables 8 and 9).

Premature Births Induced by Oxytocin.—For 1955-1956, more than 6% of all live births induced with oxytocin were premature as compared with 8.7% for all live births in New York City. On the ward services, the premature rate was 11.5%; however for those induced, the rate was higher (15.6%).

Of the 29,381 total premature live births in New York City for 1955-1956, 1,025 (3.5%) followed induction by oxytocin. Of these, 281 (27.4%) were the result of elective induction. Premature births associated with elective induction were highest in the months of June, July, August, and December. It is highly probable that labor was induced prematurely in these patients who might otherwise have gone to term (table 10).

Perinatal Mortality.—The perinatal mortality for 1955 in the induced private patients was 2.8%. For the remainder on the private services it was 2.2%. On the ward service the perinatal mortality was much higher for the induced group than for the rest (16.4% as compared with 3.8%). The much higher perinatal mortality on the ward services for the induced group may be due to the fact that oxytocin was used largely in cases in which there were complications such as toxemia, partial separation of the placenta, and other therapeutic indications.

The perinatal mortality for the spontaneous and forceps deliveries after induction (0.5 and 0.2%) is lower than for those not induced (2.8 and 1.3%). In these cases the use of oxytocin was limited to a highly favorable group where a low perinatal mortality generally prevails and where oxytocin was used largely for elective rather than for therapeutic reasons. (Perinatal mortality as herein calculated =[fetal deaths after 28 weeks gestation+infant deaths under 7 days]÷[fetal deaths after 28 weeks gestation+total live births]×1,000. Perinatal mortality data for 1958 are not available at the time of this report.)

The perinatal mortality for the induced deliveries on the private and ward services combined is higher than for the deliveries without induction. This difference is due entirely to the significantly higher perinatal mortality associated with breech deliveries and cesarean sections. For these two categories of breech and cesarean section it was observed that oxytocin was used predominantly for therapeutic indications. In a group of 206 breech deliveries where induction was used, there were 57 perinatal deaths with a perinatal rate of 27.7%. This rate is much higher than that found for breech deliveries where oxytocin was not used (16.6%). In a group of 201 cesarean sections where induction was attempted, there were 20 perinatal deaths with a perinatal rate of 10.0% as compared with a perinatal rate of 5.2% for cesarean sections where oxytocin was not used.

Puerperal Mortality.—In 1955-1956 there were 203 puerperal deaths reported; 103 fetuses were of 28 weeks' gestation or over. It is important to note that puerperal deaths have been encountered in reviewing hospital records where use of induction was not recorded on the birth or fetal death certificates, although oxytocin had been administered. Furthermore, an analysis limited to a study of deaths due to puerperal causes has its shortcomings in excluding patients who survived although they had developed serious complications after the administration of oxytocin. Several case reports are cited in which the administration of oxytocin for the induction of labor was believed to contribute to mortality.

CASE 1 (hypofibrinogenemia, amniotic fluid embolism). —A 23-year-old woman, gravida 3, para 2, blood type A, Rh+, was a private patient with an uneventful prenatal course. She was electively induced at term (40 weeks) with intravenously given oxytocin, 10 units per 1,000 cc. of 5% glucose solution. She had a rapid labor, proceeding from 1 cm. cervical dilatation to sudden precipitous delivery of a stillborn fetus, including the simultaneous delivery of the placenta, in the course of one hour and five minutes. The fetal heartbeat was stated to be normal until 10 minutes before delivery, after which time it was no longer heard. The delivery was followed by severe uterine hemorrhage with failure of the blood to clot. Visual examination of the cervix at this time revealed no evidence of laceration. The patient received 8 units of blood (4,000 cc.) and 10 Gm. of fibrinogen before good clotting resulted. This patient's blood pressure could be maintained at adequate levels only by the use of dilute intravenously given levarterenol (Levophed) bitartrate solution. A lower nephron nephrosis developed. This condition became progressively more severe, resulting in death six days after delivery. Postmortem examination revealed lower nephron nephrosis, pituitary necrosis, and pulmonary amniotic fluid embolism.

Comment.—While it has been observed that, on occasion, when oxytocin has not been used, tumultuous rapid labor will result in a condition similar to that described above, it is definitely felt that the sequence of events in this fatal case were initiated by the use of oxytocin. Similar cases have been encountered in the course of review of hospital records in obstetric services over the past several years where hypofibrinogenemia resulted after the use of intravenously given oxytocin for induction and/or stimulation of labor, particularly in toxemias of pregnancy. Many of these patients have survived with the administration of adequate fibrinogen and blood replacement. These cases have not been reported in the literature.

Case 2 (ruptured uterus).—A 27-year-old woman, gravida 7, para 4, had an uneventful prenatal course with normal laboratory findings. She was admitted to the hospital at 34 weeks' gestation with ruptured membranes and mild uterine contractions. It was stated on the record that "because of desultory ineffectual contractions" oxytocin, 10 units per 1,000 cc. of 5% glucose solution, was administered by drip induction. The presentation in this case was left occipitotransverse. The cervix was soft, 50% effaced, and 2 cm. dilated. After three hours and 15 minutes of labor the patient spontaneously delivered a 2,268-Gm. (5-lb.) living infant and immediately went into severe shock. The patient received 10 units of blood, administered under pressure, and a hysterectomy was promptly performed. Examination revealed uterine rupture with massive retroperitoneal hemorrhage. The patient died on the operating room table.

Comment.—This patient had a premature infant with a gynecoid pelvis which was adequate. It is highly unlikely that this accident would have occurred spontaneously. Although the experienced obstetrician is aware that uterine rupture may occur spontaneously, particularly with increased parity, the risk of this complication is compounded by the use of a potent agent such as oxytocin.

* In no case did labor continue for more than 24 hours.

Case 3 (breach presentation, ruptured uterus).—A 21-year-old primipara with a breech presentation, left sacroanterior, was admitted to the hospital at term for elective induction of labor. The record noted an adequate gynecoid pelvis. After three and one-half hours of "good labor" after administration of oxytocin, the patient went into shock. On examination, the fetus was recognized to be in the upper abdomen and an immediate laparotomy was performed. Approximately 3,000 cc. of blood was found in the peritoneal cavity. A living 3,200-Gm. (7-lb.) male fetus was extracted from the peritoneal cavity. It was observed that the uterus was ruptured through the fundus. The patient received 14 units of blood, and the maintenance of her blood pressure was assisted by an intravenous solution of levarterenol. The patient then appeared in fair condition with a blood pressure of 110/86 mm. Hg and pulse rate 120 per minute. However, the urine output was diminished, and 12 hours postoperatively the patient's skin was cold and clammy. The hematocrit reading was 38%, blood pressure 100/70 mm. Hg, and blood platelet count 112,000 per cubic centimeter. Although the blood clotted and the prothrombin time was normal, the patient died 27 hours after operation due to massive retroperitoneal hemorrhage which was demonstrated at postmortem examination.

Comment.—This case illustrates the outcome of injudicious elective induction of labor with oxytocin in a primipara with a recognized breech presentation, resulting in a ruptured uterus.

Additional cases of ruptured uterus have been encountered in association with the use of intravenously given oxytocin for induction. Space does not permit the detailed accounts of at least 12 known cases of serious complications of ruptured uterus, severe hemorrhage with or without hypofibrinogenemia, and amniotic fluid embolism after the elective induction of labor with oxytocin. Most of these patients fortunately survived after prompt detection of the complication and immediate therapy. It is important to note that the above abstracted cases occurred on well-equipped obstetric services with qualified obstetricians.

Although all experienced, well-trained obstetricians are aware of the potential danger in the use of oxytocin, errors in judgment in the use of this drug and its occasional unpredictability will continue to add to the catastrophies presented.

Comment

For the years 1955 and 1956 oxytocin was used for the induction of labor in 4.9% of all deliveries in New York City, as reported on the birth certificates, and in 6.6%, as reported in the hospital questionnaire form. These figures are much higher than those reported by Hellman and co-workers [5a] in their analysis of 63,276 deliveries in 10 hospitals from 1951 through 1955 wherein it was stated that intravenously given oxytocin was used in 1.8% of the cases for the induction of labor. Elective induction accounted for 52% of all the oxytocin-induced deliveries on private services in New York City.

An outstanding finding which emerged from analysis of the data is the occurrence of peaks in the use of oxytocin in private patients for the induction of labor in the months of July, August, and December. This highlights the fact that it is extensively used for the convenience of the obstetrician and/or the patient. Various reports [6] from the literature indicate that convenience is a factor in the elective use of oxytocin for the induction of labor. Hellman states, "It seems highly improbable that these well trained and seasoned obstetricians would use a potentially dangerous drug to satisfy personal convenience." Willson,[7] in a study of 180 cases of elective induction with intravenously given oxytocin, concludes that its use is seldom justified in normal pregnancy.

The following factors are related to the use of oxytocin.

Ruptured Uterus.—It would appear that, in the puerperal deaths herein described, the use of oxytocin led to rupture of the uterus. Case reports corroborate the sequence of ruptured uterus occurring after elective use of oxytocin.[8]

Uterine Hemorrhage.—Within the limitations of the data obtained from certificates, the problem of postpartum or intrapartum hemorrhage is not ascertainable except as associated with a puerperal death. Sotto and Wildhack[9] indicate a higher proportion of severe hemorrhages after the elective use of oxytocin. The question of hypofibrinogenemia has been raised and is suggested in our review of puerperal deaths.

Perinatal Mortality.—Much more information needs to be added to our findings, which suggest that in cesarean section and breech deliveries the prior use of oxytocin appears to increase mortality. Several reasons may be postulated for this:

1. Where oxytocin was given intravenously, an indicated cesarean section was possibly delayed, resulting in fetal distress. 2. In patients with borderline pelvic measurements, a trial of labor may be unduly prolonged when oxytocin is used and result in fetal damage. This is in agreement with the views expressed by Cosgrove and Weaver.[10] 3. The use of oxytocin may result in fetal distress by causing prolonged uterine contraction or tumultuous labor.

On the other hand, although mortality in the case of spontaneous delivery after use of oxytocin is not increased, a matched control group is needed to compare induced spontaneous deliveries with those not induced, where the same socioeconomic factors and level of obstetric care prevail.

Fetal Distress.—Trauma to the infant, short of being fatal, is not ascertainable from certificate data. Seven cases of fetal distress after the elective use of oxytocin which necessitated cesarean section have been mentioned above. This would substantiate the belief that occasionally the fetus is subjected to needless damage. Long-term follow-up of such individuals would be of invaluable help.

Many of the questions raised here regarding the use of intravenously given oxytocin and its effect on the mother and upon the infant remain unanswered. It is hoped that this study will stimulate further investigations on the use of oxytocin for acceleration and/or induction of labor.

Summary

An analysis has been made of the use of intravenously given oxytocin (Pitocin) in New York City for 1955-1956, as ascertained by birth and fetal death certificates and by questionnaire. Oxytocin was used for induction in 4.8% of all live births, as determined from certificate data. Induction of labor with intravenously given oxytocin occurred primarily on the private services of the voluntary hospitals. Of all elective inductions, 95.1% occurred on private services. Labor was induced by use of oxytocin almost five times more frequently in the private patients than in the ward patients.

A geographical variation was noted in the frequency of use of oxytocin for the induction of labor. Of the five boroughs in New York City, Brooklyn was recorded as having the highest incidence. A marked seasonal variation in the use of oxytocin was observed on the private services. The peak months were July, August, and December. Elective induction was chiefly responsible for the seasonal variation observed. No such variation occurred on the ward services.

Of the 1,025 premature infants born after the use of oxytocin, 281 (27.4%) were born after elective induction. The highest incidence of premature births after elective induction occurred in June, July, August, and December. The infant mortality rate was almost twice as high for infants delivered by cesarean section where oxytocin had been previously used as compared with those delivered by cesarean section where previous induction had not been attempted. In several cases of puerperal mortality oxytocin appeared to have initiated an unfortunate sequence leading to rupture of the uterus, hypofibrinogenemia, and uterine hemorrhage.

PREVENTION OF INFECTION OF URINARY TRACT IN PRESENCE OF INDWELLING CATHETERS

DESCRIPTION OF ELECTROMECHANICAL VALVE TO PROVIDE INTERMITTENT DRAINAGE OF THE BLADDER

Edward H. Kass, M.D., Ph.D., Boston

and

Harold S. Sossen, B.S., M.Ed., Dover, Mass.

Catheters kept in the urinary bladder as long as four days provoke bacteriuria in almost every case. The technique here described prevents this complication by continuous irrigation with 0.25% acetic acid through a catheter with three lumens. One passage permits distention of the retaining balloon; the other two passages are for inflow and outflow. The method was successful in more than 100 patients. The rate of inflow of the acetic acid solution was roughly equal to that of urine production, but it was adjusted so that the effluent was kept at pH 5.0 or less and the bacterial count at less than 1 million per milliliter. Outflow was interrupted periodically by use of an electromechanical valve to permit filling of the bladder and avoid prolonged contraction. In some patients it was possible to leave the catheter in situ as long as 60 days without inducing bacteriuria.

When an indwelling catheter has been in the bladder for 24 hours, the incidence of bacteriuria in patients whose urines were previously sterile is about 50%. After four days of constant catheterization 98-100% of patients develop 100,000 or more bacteria per milliliter of urine.[1] The hazards of catheterization have been widely recognized and the medical profession has been cautioned against the indiscriminate use of indwelling catheters.[2] On the other hand, the indwelling catheter is often indispensable to the management of many clinical conditions. The desirability of using the indwelling catheter without inducing bacteriuria is manifest.

The bacteriuria that follows the use of indwelling catheters is due to the constant entry of bacteria into the bladder when the catheter is in place. The probable route of entry of the bacteria is the film of exudate that forms in the urethra in response to the presence of the catheter.[3] This film is an excellent culture medium for bacteria and links the fecal

of entry t been achieved, although it is
reasonable ppose that proper choice of the
diameter of a catheter and careful technique in insertion may delay the entry of bacteria. Cleansing the bladder of bacteria promptly after they have entered it can be achieved if the bladder is rinsed with an antibacterial solution so that bacterial multiplication cannot occur. If antibacterial solutions are to be useful for such a purpose, they should be nontoxic, relatively inexpensive, active against all of the bacterial species that may be found in the bladder, and unlikely to permit resistant strains to emerge.

Acetic Acid as Bacteriostatic Agent

Acetic acid satisfies these conditions. It is a potent bacteriostatic agent. At pH 5.0, which is not lethal for most pathogens of the urinary tract, as little as 0.01 M (0.06%) acetic acid will sterilize a broth culture of Escherichia coli. None of the urinary tract pathogens so far tested has resisted 0.02 M acetic acid at pH 5.0. The antibacterial action of organic acids has been known for many years, and acetic acid has been a standard rinsing solution in douches and bladder rinses. Its limitations have been few, but they are critical. Chief among these is that the antibacterial action of acetic acid is apparently linked to the number of unionized molecules in solution; if the pH is permitted to rise, the antibacterial action falls off sharply. Furthermore, the antibacterial action of acetic acid requires prolonged contact between the acid and the bacteria, so that more or less continuous presence of acetic acid in the bladder must be maintained.

The simplest means for providing continuous administration of acetic acid is by the use of an ordinary double-lumen indwelling catheter. This type of catheter actually has three lumens: one for distending the retaining balloon and two running from the interior of the bladder. A solution of 0.25% acetic acid (prepared by adding 2.5 ml. of glacial acetic acid to 1 liter of sterile water) drips into one of these tubes, and the mixture of acid and urine leaves through the other. The rate of flow of the acid is adjusted so that the effluent is kept at pH 5.0 or less and the bacterial count at less than 100,000 bacteria per milliliter of urine. The pH can be tested by inserting a strip of pH paper, such as nitrazine paper, into the effluent. The bacterial count is determined by microscopic examination of a stained drop of uncentrifuged effluent. If no bacteria are seen, the bacterial count is generally less than 100,000 per milliliter.[1] The bacterial count can be determined more precisely by standard pour plate colony counts of serial dilutions of the effluent. Only rarely, if adequate amounts of acetic acid are used, will any bacteria be found in the culture.

The procedure outlined above is highly effective if the flow of acetic acid is sufficiently rapid. Ordinarily a flow of 0.25% acetic acid equal to the rate of urine flow is adequate. When a highly alkaline urine is encountered, as in Proteus infections, the rate of flow may be increased. If necessary, a higher concentration of acetic acid, such as 0.5%, may be used. In extremely difficult situations, in which the urine has remained alkaline despite rinsing of the bladder with acetic acid, a stronger acid, such as 0.25% lactic acid, may be used to acidify the urine to pH 5.0 or less. Acetic acid may then be substituted for lactic acid, since on a molar basis acetic acid is about 10 times as active as lactic acid as a bacteriostatic agent at pH 5.0.

Drainage System for Bladder

The continuous drainage system just described will maintain the bladder free of bacteria if properly managed. However, after two or three days, the bladder may become so contracted that when the catheter is removed the patient will often complain of frequency and marked pelvic discomfort, because of the small volume of the bladder. The effects of contraction of the bladder may be circumvented by providing intermittent filling of the bladder to a physiological volume. This may be done effectively by the use of tidal drainage, which supplies both a physiological stimulus and a constant supply of antibacterial fluid to the bladder. Unfortunately, tidal drainage requires an apparatus that is sufficiently complex to have aroused substantial resistance from house staff and nursing staff alike. Some simplification of this approach is desirable. In addition, tidal drainage often will not work in individuals with hypotonic or irritable bladders.

The two-way catheter drainage system that has been described may be modified to permit the bladder to increase its volume. Initially, the effluent tube was clamped and released for only five minutes every hour, permitting accumulation and periodic discharge of the contents of the bladder. In this manner, the bladder could be distended to hold a volume of several hundred milliliters, depending upon the rates of flow of urine and of acetic acid into the bladder. However, the personnel problems involved in the manual control of the clamp were such that it seemed desirable to have this task performed electromechanically.

Electromechanical Device

An electromechanical device for controlling the discharge of fluid from the bladder is shown in the figure. It consists of a motor-driven timer, which actuates a solenoid-operated clamp. The effluent tube is placed within the clamp, which is in the open position when no electrical current is flowing. When the switch is turned on, the clamp shuts and no release of fluid from the bladder can occur. The timer opens the clamp at periodic intervals. The present apparatus, which is the result of testing of several alternatives, provides four timing cycles. The clamp may be kept closed for 55 minutes and opened for 5 minutes, or it may be closed for 25 minutes and opened for 5 or closed for 15 minutes and opened for 15. The device can be hooked to the bedrail or bedspring, is virtually noiseless, and is "fail safe" (any mechanical or electrical failure causes the clamp to open automatically).

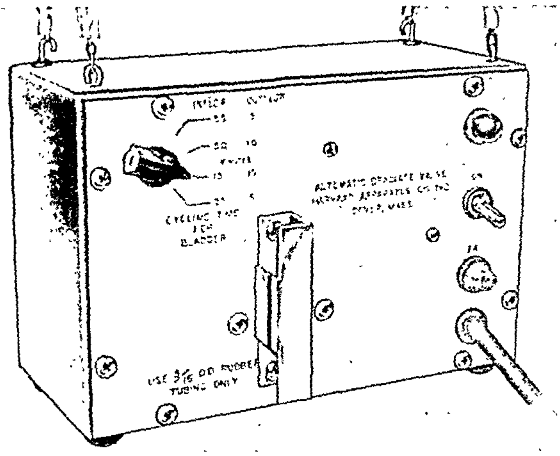
The apparatus has been used in more than 100 patients who have required indwelling catheters. Less than 10% of patients whose catheters have been managed by this method have developed bacteriuria, whereas 100% of patients given saline instead of acetic acid have developed bacteriuria.[4] Patients with indwelling catheters have been maintained for as long as 60 days by this procedure without any bacteria being found in the bladder.

In practice, one lumen of the indwelling catheter is attached to a bottle fitted with a dropping device and containing 0.25% acetic acid. The rate of flow into the bladder is controlled by an ordinary tubing clamp. The effluent from the bladder is collected in a receptacle beneath the bed. The rubber tubing passing from the catheter to the collecting bottle is placed in the clamp of the electromechanical valve. For most purposes the cycle is kept at 55 minutes closed and 5 minutes open. If the capacity of the bladder is small, a shorter cycle may be used. The 15-minute cycle has been particularly useful in the management of pyelostomies and in dealing with indwelling catheters in small children.

No important difficulties have arisen thus far in the use of this device. The clinical results, which will be the subject of a more detailed report elsewhere, have indicated that the acid rinse as presently used induces microscopic hematuria in about 5% of patients. About 1% develop pelvic distress and gross hematuria. Further improvements in the nature of the antibacterial rinsing fluid are expected to diminish the incidence of these local reactions.

Summary

In order to avoid infection of the urinary tract during indwelling catheterization, the bladder should be rinsed constantly with an antibacterial solution. Dilute acetic acid (0.25%) is an adequate solution if its flow is sufficiently rapid to provide a pH of less than 5.0 and bacterial counts in the urine of less than 100,000 bacteria per milliliter. The acetic acid rinse is conveniently administered through one lumen of a two-way catheter and the acidified urine is discharged through the other. An electromechanical valve may be used for providing intermittent drainage of the bladder simply and reliably.



Electromechanical device for controlling discharge of fluid from bladder.

AMNESIA-ANALGESIA FOR THE MANAGEMENT OF CHILDREN TOO YOUNG TO COOPERATE

FURTHER OBSERVATIONS

John S. Lundy, M.D., Rochester, Minn.

Some months ago I[1] reported the results of application of a procedure which my colleagues at the Mayo Clinic in 1957 asked me to develop for the management of cardiac catheterization in children too young to cooperate. In that report I based my observations on experience with 36 children, 9 months to 12 years old, who had cardiac defects and defects of the great vessels. Fifty-one other children were managed by the same procedure, plus the use of anesthesia with nitrous oxide, oxygen, and ether, preparatory to tonsillectomy and adenoidectomy or operations on the eye. My series now includes 133 children who underwent cardiac catheterization and 100 who underwent other operations which demand a degree of tranquility and cooperation from the patient.

It is emphasized again that the procedure in question does not consist primarily of anesthesia alone. Rather, it is a special application of both analgesia and amnesia. The important aspect is the fact that the agents used do not interfere with the test or examination being carried out, as they would if they were primarily anesthetic agents administered, particularly by inhalation. The patient breathes either air or oxygen throughout the test or examination, so that it is possible for the physician during cardiac catheterization, for instance, to interpret physical data readily, to carry out Van Slyke tests, and to reach an unimpeded decision as to the lesion or lesions present, provided that technical difficulties arising during the course of the test do not complicate matters unduly.

Cardiac catheterization, like many other diagnostic and therapeutic procedures, poses especially difficult problems for the anesthesiologist when the patient is too young to cooperate. The procedure here outlined consists of a sequence of steps whereby the requisite degree of tranquility, analgesia, and amnesia can be attained without interfering with the tests or examinations being carried out. Upon this background it is possible to superpose anesthesia with nitrous oxide, cyclopropane, or ether for short periods when necessary. Exact calculation of dosages is essential. Applied in 133 cases of cardiac catheterization and 100 comparable operations of other kinds, this plan has reduced to a minimum the respiratory and other reflex disturbances which otherwise make it difficult to interpret results.

Method

The mechanics of the procedure are set forth in the table. First of all, the pediatrician furnishes an estimate of the degree of risk of cardiac catheterization, based on a scale of 1 to 4 in which 4 is the gravest risk. Next, the parents or relatives of the child are told specifically what is to be done and what the risk is. Then I weigh the child myself. This is of prime importance, since experience has shown that in some instances only estimates of body weight will be furnished by the referring physicians. Catheterization of the heart then proceeds, after which I receive the child into my care, where he remains until I send him to the hospital or until the parents or relatives take him home.

The three factors are the weight of the child, the passage of time checked carefully by the clock, and abatement of the movements of the child. The chief hazard in this method involves exact measurement of the dose of the drug from the container in which the manufacturer supplies it. The smaller the child, the more difficult it is to measure exactly the required dose. Only recently have I been able to obtain a mixture of levorphanol (Levo-Dromoran) tartrate and levallorphan (Lorfan) tartrate compounded in such a manner as to assure me that 0.2 cc. per 10 lb. of body weight of the child is the correct dose. I also have been able to obtain promethazine (Phenergan) hydrochloride in a correspondingly correct dilution and alphaprodine (Nisentil) hydrochloride and proheptazine (Wy 757) as well. Each time the formula has been modified, the results have been unsatisfactory from the standpoint of both the management here described and the test itself.

To calculate the dose of thiopental (Pentothal) sodium to be administered rectally, the actual weight of the child in pounds is used. To calculate the dose of drugs to be administered by injection, the weight in pounds generally is lowered to the next even number in units of 10 or to make the figure in units of 10 or halfway between. That is,

---

From the Section of Anesthesiology, Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

if a child weighs 41 lb., the weight employed in the calculation would be 40 lb. If the weight were 46 lb. the figure 45 would be used for calculation of the dose, or if the weight were 49 lb. the figure 50 might be used. Any arbitrary increase in the weight for purposes of calculation of the dose can be used only when the patient is relatively robust.

Some children do not, because of intrinsic physiological factors or deficiencies of which we are not yet aware, tolerate the procedure well, and difficulties will arise when such patients are managed by the method described. Some vomit once or twice after they awaken, and this applies to those who have not undergone cardiac catheterization as well as to those who have, indicating that the vomiting may not be referable to the heart. Some of the premonitory signs are known. A child who holds his breath probably will not adapt himself satisfactorily to the procedure, for such an action has been seen to exert an adverse effect on the circulation. Heavy crying on the part of a child also is a sign of impending difficulties with the circulation. A child who is in a very unsatisfactory state of debilitation obviously is not an ideal candidate for the method.

The blood pressure of three children who manifested these signs decreased precipitately to 22, 28, and 98 mm. Hg; one died 12 hours after cardiac catheterization, one died 15 hours after the procedure, and one died immediately after the procedure. Studies are under way to elicit additional causative factors in such difficulties.

Following is an illustration of a difficulty that can arise. One of the assistants, without consultation, decided to administer a small quantity of thiopental sodium intravenously through the cardiac catheter. The result was a sudden depression, with a decrease in blood pressure which is entirely

OUTLINE—MAY BE HAZARDOUS IF NOT FOLLOWED EXACTLY

NOTE: BEFORE CATHETERIZATION, THE ANESTHESIOLOGIST HIMSELF SHOULD WEIGH THE PATIENT AND EXPLAIN TO THE RELATIVES WHAT IS TO BE DONE. IN THE COURSE OF CATHETERIZATION, HE SHOULD GO OUT AND REASSURE THE RELATIVES NOW AND THEN.

Procedure:

	Step	Agent*	Dose		Route	Remarks
			Mg.	Relation to Body Wt.		
Preoperative	1	thiopental (Pentothal) sodium	15	per 1 lb.	rectal	
	2	Wait 5 to 10 min. for thiopental sodium to take such effect that patient will not remember IM injections of step 3				
	3	Step 3 consists of injection, at one time, of 4 drugs, all mixed together in one syringe, as follows (a, b, c, d):				
	a	levorphan (Levo-Dromoran) tartrate	0.2 WARNING see remarks	per 10 lb.	IM	Even if a child weighs more than 100 lb., if he is 10 yr. of age or less, dose of levorphan MUST NOT EXCEED 1 mg. Give NO additional levorphan for same procedure
	b	levallorphan (Lorfan) tartrate	0.1	per 10 lb.		Mixture given in step 3 is not clear. Do not be alarmed by milky appearance. It can be used without being cleared. However, it can be cleared by mixing with 1 cc. of 1% procaine hydrochloride
	c	promethazine (Phenergan) hydrochloride	2.0	per 10 lb.		
	d	proheptazine (Wy 757) or alphaprodine (Nisentil) hydrochloride	1.0	per 10 lb.		
	4	Wait 20 min. for analgesia, prospect of amnesia, or both to develop				
Operative	5	Infiltrate with local anesthetic line of incision for venostomy				
	6	proheptazine or alphaprodine	1.0	per 10 lb.	IM	This step is necessary IF CHILD IS RESTLESS, as most children are
	7	*Wait 5 min. in expectation that child will become sufficiently quiet to permit initiation of cardiac catheterization and will remain quiet for 1 to 2 hr.* If child is not sufficiently quiet for cardiac catheterization to start, or if catheterization is in progress and child becomes unduly restless, give following:				
	a	proheptazine or alphaprodine	1.0	per 10 lb.	IM	Dose may be given again at intervals of 45 min. to allay restlessness
	b	If patient moves within 1¾ to 2 hr. after the first enema of thiopental (see step 1), and if the procedure is expected to take 3 to 5 hr. (NOT if procedure is expected to be short: i. e., 2-3 hr.) repeat step 1 and, if necessary to keep patient quiet, step 7a.				
Postoperative	8	After catheter tip has been removed from heart, but before it has been removed from vein, give following drugs:				
		bemegride (Megimide; 3-ethyl-3-methylglutarimide) and amiphenazole (Daptazole)	10 ABSOLUTE 30†	WITHOUT RELATION TO BODY WEIGHT	via catheter	*Five min. after this dose is given, if necessary to arouse patient, same dose, BUT GIVEN INTRAMUSCULARLY, may be used once again*
	9	Now, because of congenital cardiac defect and stress of procedure, begins a period that may be HAZARDOUS. Usually, about 1 min. after bemegride is given, patient will arouse sufficiently to answer questions. Thereafter, for 1 to 2 hr., he should be in state much resembling normal light sleep, from which he can be easily aroused. BUT if BLOOD PRESSURE FALLS and CYANOSIS develops, give following:				
	a	oxygen			inhalation	*Five min. after this dose, if necessary to raise blood pressure more and to produce signs of arousal, same dose by same route may be given once again.* Then, if respiration is not good, give 0.1 mg. of levallorphan intravenously
	b	*mephentermine (Wyamine) sulfate* or methylphenidate (Ritalin) hydrochloride	7.5 ABSOLUTE 7.5 ABSOLUTE	WITHOUT RELATION TO BODY WEIGHT	IM	

---

* Until the manufacturers concerned offer the following agents in the precise quantities required for the procedure in question, I use the following proportions:

levorphan	1.0 mg.
levallorphan	0.5 mg.
alphaprodine	5.0 mg.

solvent to make 1 cc.; administered in a dose of 0.2 cc. per 10 lb. body weight

proheptazine or alphaprodine	5.0 mg. (steps 6 and 7a)

solvent to make 1 cc.; administered in a dose of 0.2 cc. per 10 lb. body weight

promethazine	10.0 mg.

solvent to make 1 cc.; administered in a dose of 0.2 cc. per 10 lb. body weight

† If child weighs less than 50 lb., dose of amiphenazole may be reduced to 15 mg.

OUTLINE—MAY BE HAZARDOUS IF NOT FOLLOWED EXACTLY

unsatisfactory as far as the test is concerned. Moreover, such an action is quite unsatisfactory to me, since I have no way to control the dose administered. Therefore, further intravenous injections have been disallowed. If the child is too active, thiopental sodium is administered again by rectum.

One of the questions that has been answered more or less since the preliminary report[2] has to do with the fact that about 10% of these children are resistant to the action of the thiopental sodium enema and the hypodermic injection. It now appears certain that, if the child is still crying and moving 15 minutes after the first rectal administration of thiopental sodium and also 10 minutes after the hypodermic injection, a second full dose of thiopental sodium should be administered rectally. In only one instance in this series was the child sufficiently unconscious that five minutes after the rectal administration of thiopental sodium the child appeared to have an overdosage. In this case nothing further was used in a procedure that lasted two and one-half hours. This emphasizes the importance of the body movements of the child.

A possible criticism of this method might be that it causes the patient to sleep for two or three hours after the test has been completed. However, such an effect is not hazardous, and, if it constitutes a deficiency, the disadvantage is more than outweighed by the enhanced safety which the method provides.

I may point out that in this series I have had only two or three patients who were relatively overweight. Most of the patients have been underweight, and this may explain why the method has been so satisfactory. Nevertheless, even when the patient is overweight I am convinced that the statement, "Even if the child weighs more than 100 lb., if he is 10 years of age or less, the dose of levorphan must not exceed 1 mg.," is correct and should be observed scrupulously.

Applications Other Than in Cardiac Catheterization

This method also has been applied in almost 100 procedures other than cardiac catheterization. Irradiation therapy for retinoblastomas of the eye, heretofore a difficult anesthesia-analgesia-amnesia problem, is well suited to the technique I have described. There are three phases of this problem: (1) an initial period of surgical anesthesia of moderate length for implantation of seeds or needles, (2) an intermediate period of amnesia-analgesia extending several hours, during which the implant must not be disturbed, and (3) another period of surgical anesthesia of relatively short duration for the removal of the seeds or needles.

Thiopental sodium is administered rectally to the child on a basis of 15 mg. per pound of body weight. When a light sleep is evident, these agents are administered intramuscularly: 0.2 mg. of levorphanol, 0.1 mg. of levallorphan, 0.1 mg. of alphaprodine, and 2.0 mg. of promethazine, each per 10 lb. of body weight. This is an exacting technique: reference should be made to the accompanying table for the details. Venipuncture can be done with ease at this point, preferably with a plastic needle, so that fluids may be given continuously.

The patient is then anesthetized by gradually increasing the concentration of ether in an oxygen (3 liters) and nitrous-oxide (7 liters) mixture until a depth of anesthesia appropriate for intubation is obtained, at which time an endotracheal tube is passed orally. Surgical anesthesia is maintained while the radon seeds are implanted. After this, maintenance of inhalation anesthesia is discontinued and the endotracheal tube is removed. The child will then remain in a state of amnesia-analgesia for several hours without disturbance of the implanted radon or radium.

When radon or radium is to be removed, the patient again is anesthetized. Since this is a relatively short procedure, cyclopropane is the anesthetic agent of choice and endotracheal intubation usually does not appear justified. The recommended initial mixture is 6 liters of nitrous oxide, 3 liters of oxygen, and 1.5 liters of cyclopropane, administered by mask. When a surgical depth of anesthesia is reached, a tube is introduced into the nostril, away from the surgical field, and the other nostril and the oral airway are occluded. Inhalation anesthesia is maintained through the nasal tube, and the mixture of cyclopropane is adjusted to that minimal concentration which will be adequate for anesthesia. At cessation of the operation ventilation is begun by the administration of 100% oxygen. The child will arouse quickly but will lapse into a light sleep if left undisturbed for the immediate postoperative period.

For example, a 2-year-old child with retinal blastoma was put to sleep according to the method I have described and received nitrous oxide and oxygen while the eye was exposed and the radium seeds were implanted. In this case the rectal administration of thiopental sodium (100 mg. per cubic centimeter) was followed in exactly five minutes by injection of the four drugs concerned. Respiration was depressed for one and one-half minutes, no doubt as a result of the peak effect of the five drugs used. In this instance results probably would have been better had I waited a few more minutes before proceeding with the hypodermic injection. Three and one-half hours later the operation was concluded by exposure of the eye and removal of the radium. Under such conditions it probably would be wise to do venipuncture and to administer fluids intravenously throughout the procedure.

By means of this technique a difficult anesthetization problem is handled with ease. A minimum of depression referable to any one single agent will be noted, with a consequent minimal risk to the patient. This again emphasizes the value of the concept of balanced anesthesia.

Comment

I have been assured by pediatricians who refer such patients for the test and by physiologists who do the test that they are entirely satisfied with the results of this method of management, since it helps them to avoid technical errors which might otherwise make it difficult to interpret their data. The excellent respiratory action which the method provides is the result of the effect of levallorphan tartrate.

CLINICAL NOTES

SAFETY CLOSURE CAPS

SAFETY MEASURE FOR PREVENTION OF ACCIDENTAL DRUG POISONING IN CHILDREN

Jay M. Arena, M.D., Durham, N. C.

The accidental ingestion of drugs causes 35% of deaths from poisoning in children 1 to 5 years of age. In this age group the incidence of poisoning from drugs is, however, far greater than that from household agents. Mellins and co-workers[1] reported the incidence of drug poisoning alone from the Chicago Poison Control Center as 50.6%. Recent figures from the National Clearing House, as reported by Cann and associates,[2] showed that 50% of the 4,000 cases reported from 29 poison control centers were due to the ingestion of drugs. Figures from the New York Poison Control Center are even higher—an amazing 70%.[3]

In 1956 over 3.5 billion dollars was spent for drugs in the United States, so there is little wonder that poisoning is so frequent in infants and children who learn by exploration, questioning, sampling, and trial and error. They are particularly susceptible to the accidental ingestion of brightly colored, attractively shaped and packaged, sugar-coated drugs of all kinds. This being the case, it should be apparent to everyone that all available safety measures and precautions should be utilized. It is imperative that physicians give more than lip service to this problem and that they stop suggesting that education is the only means of prevention. Precautionary labeling and safety closures are good measures, among others, in the prevention of these tragic accidents.

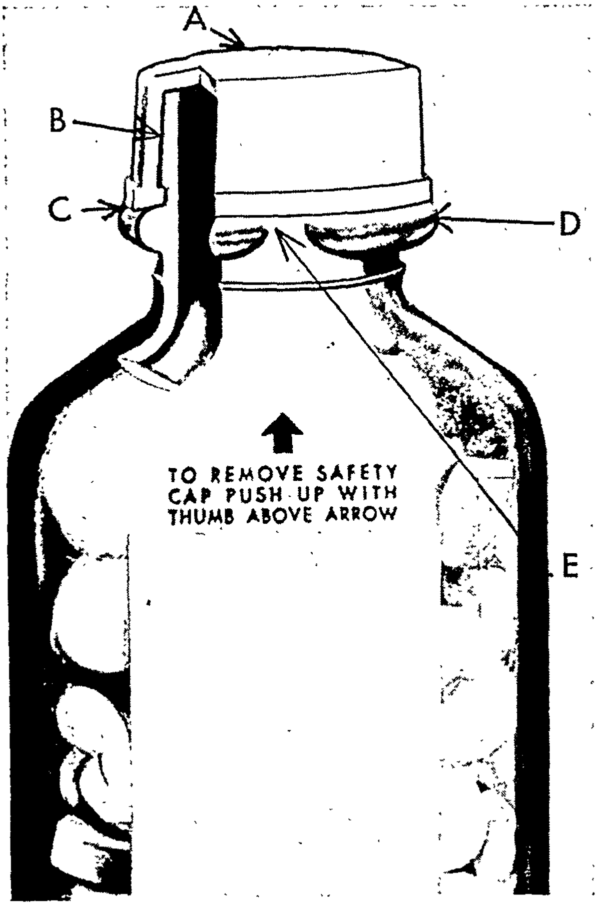
After trying out more than 14 different types of safety caps over a period of three years, two were finally selected for comparison with the conventional screw cap in 1,600 representative homes with children under 5 years of age. The objective of this survey was to determine which of the three closures would be most effective in reducing the chances of small children gaining access to aspirin in the containers kept in the home. At the same time, it also was necessary for these safety caps to be designed and constructed so that mothers could remove and replace them with a reasonable amount of ease and convenience.

Results of Survey

The following information was obtained at the completion of the survey: The A and B closures were equally difficult to remove by over 93% of the children in the survey, as compared to 66% in removing the screw cap. Only 33.8% of the children had difficulty in replacing the B closure, as compared to 56.8% for the A type and 38.9% for the screw cap. These figures imply that older inquisitive children, in replacing the B cap easily, can conceivably prevent younger infants in the family from gaining access to the contents of the respective bottle.

In the survey of mothers, difficulty in removing the closure was affirmed by over 67% for the A type, 16% for the B type, and 49% for the screw cap. When asked, "In regularly replacing the cap, do you feel that it goes on securely each time?" affirmative answers were given by 60% for the A type, 97% for the B type, and 81% for the screw cap.

As a safety measure, the difficulty that mothers encountered in replacing the A cap and the screw cap (i. e., resealing the bottle) is more significant than their difficulty in opening them, since a loose cap can mean an open container.



Safety closure of choice: *A*, wording on top, "Keep bottle out of children's reach," for adult caution; *B*, glass tapers to allow easy cap replacement; *C*, grip of cap under glass for tight seal and reseal; *D*, wide-design special glass bead, to help reduce biting off or pulling off by children; and *E*, bead opening (in front and back) for adult "thumb-off" removal.

The children's difficulty in removing the B cap and their mothers' ease in removing and replacing the B cap made it the closure of choice from the manufacturers' and the families' standpoint (see figure).

Although questionnaire responses are often disapproved of for definitive statistical data, and however impressive these figures are, one must always keep in mind that over 6% of the children under 5 years of age in the survey were able to remove, in one way or another, the B safety cap without great difficulty—many by using their teeth. At any rate, it must be realized that, regardless of what safety measures and precautions are taken, some children will circumvent them in any case.

Summary and Conclusions

A survey of 1,600 families has indicated that a safety closure of plastic is not only practical for manufacturers and mothers but also, if used on all packaged and prescribed medicaments, is a child-safety measure of real importance. The widespread adoption of a safety closure of some type for all drug containers in common home use could reduce in great part the morbidity and mortality from the accidental, experimental, and innocent ingestion of potentially poisonous drugs. Hospitals should lead the way in dispensing drugs only in bottles with a safety closure.

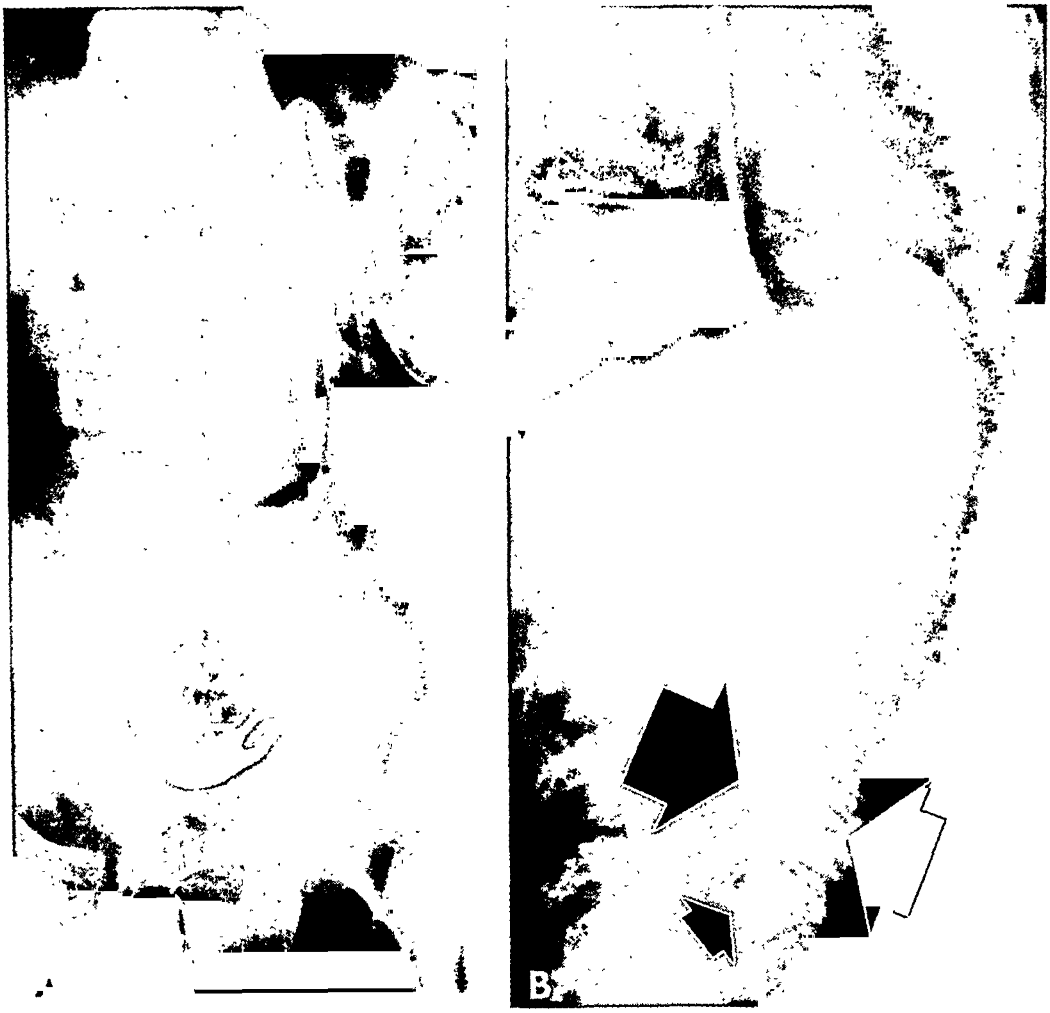
FORMALDEHYDE AS A FUMIGANT.—Disinfection by formaldehyde fumigation, unless it is to be inconveniently prolonged, has not the same margin of safety as disinfection by heat or chemical agents in solution. Formaldehyde should not, therefore, be used when any more certain method can conveniently be applied. We should not recommend it for any application where the killing of all pathogenic organisms is imperative, e.g. for surgical instruments, or the disinfection of the bedding of smallpox patients. The three applications for which formaldehyde seems most suitable are the disinfection of: (1) Rooms from which fabrics have been removed. A gas or vapor is commonly the only possible agent for this purpose. (2) Small objects which cannot be heated or wetted without damage, such as respirators, leather goods, boots, and toys not made of fabric. (3) Mattresses and woolen blankets. If these are spread out to allow access of the gas, surface disinfection is possible at room temperature, but if disinfection of the interior of the mattress or of folded blankets is required, some form of heated chamber must be used. —The Practical Aspects of Formaldehyde Fumigation, *Monthly Bulletin of the Ministry of Health,* December, 1958.

ILEAL INTUSSUSCEPTION AS RESULT OF INTESTINAL INTUBATION

Maxwell H. Poppel, M.D.
and
Bertram Brinsley, M.D., New York

The long intestinal tube commonly employed in a wide variety of conditions has been in use for about 20 years. The single lumen tube was introduced in 1944, at which time mercury began to replace air in the tube's bag.[1] The complications of intubation have been discussed by many authors. The particular one reported in this paper is rare. Smith,[2] reporting on 1,000 intubations, failed to observe a single case of intussusception. Nichols,[1] using the Harris tube, had one case. Dunn and Shearburn [3] quote three cases from the literature and add one case of their own. Wangensteen [4] and Cantor and Reynolds [5] mention the long intestinal tube as a rare cause of intussusception.



A, mercury bag at site of obstruction before administration of diatrizoate. *B*, left lateral view with diatrizoate showing mercury-filled bag as part of intussusceptum (*small arrow*) and widened loop of ileum distal, but located above, acting as intussuscipiens (*large arrows*).

Recently such a complication occurred in one of our patients. We are reporting this case because it clearly visualizes the cause and effect and, to our knowledge, possesses the best illustrations of its kind.

Report of a Case

A 50-year-old man was first admitted in September, 1958, with a presenting complaint of abdominal pain of three days' duration. His history included a duodenal ulcer of 10 years' duration and partial gastrectomy 4 years prior to admission. Since then he had had intermittent abdominal pain. Three days prior to admission he experienced continuous left lower quadrant pain with vomiting of bile-stained fluid. He had fever and leukocytosis. A diagnosis of small intestinal obstruction was made and laparotomy performed the same day. Findings at operation were negative, even though special attention was directed to the entire small intestine.

From the Department of Radiology of the New York University–Bellevue Medical Center.

The postoperative course was uneventful until the ninth day, when the patient complained of abdominal cramps. Abdominal roentgenography revealed small intestinal distention with fluid-filled loops. Decompression of the intestine with a Cantor tube was attempted for four days. Diatrizoate (Hypaque) sodium study through the tube then revealed a complete obstruction in the ileum, with the mercury bag impacted at this site (see figure).

The roentgenologic findings indicated intussusception. The loop containing the mercury bag acted as part of the intussusceptum, while the small intestine loop just beyond was widened and acted as the intussuscipiens.

Immediately after the diatrizoate study he was reoperated on and an ileo-ileo-ileal intussusception was found and reduced, and the involved segment was resected. No significant gross abnormality was noted. The postoperative course was uneventful. The patient was discharged on the 13th postoperative day. Biopsy of the removed ileal segment revealed submucosal edema.

Wangensteen[4] reports intussusception as accounting for 0.4% of all cases of intestinal obstruction. The rarity of intussusception, especially in adults, may be appreciated from the statistics quoted by de Cesare[6]: of 113,351 hospital admissions in Duluth, Minn., there were 22 cases of intussusception but only 1 was in an adult; in 529,897 admissions to the Massachusetts General Hospital, from 1887 to 1946, there were 146 cases of intussusception, of which 43 were in adults.

Deterling and others[7] reported 40 cases of intussusception in adults. In five cases there was evidence that the intussusception was caused by the presence or withdrawal of a long intestinal tube. The clinical and x-ray features that they found most reliable were (1) obstruction to the free flow of barium, (2) marked narrowing of the valvulae at the site of obstruction, (3) gradual narrowing of the lumen proximal to the lesion, (4) local widening of the intestine with semicircular mucosal markings (concentric ring or spiral sheath), (5) palpable mass at the site of obstruction, and (6) changes in position and shape after defecation. In our case findings the first three features were present.

The vast majority of intussusceptions occur in infants, but a small number (5%) occur in adults. In contradistinction to most cases in children, an immediate cause for the intussusception is usually found in the adults, such as tumors or other pathological states of the intestine or its attachments. Among the rarest is an intussusception caused by foreign body or intestinal decompression tube. A search of the American literature reveals only 11 previous case reports involving a tube. The exact mechanism by which a tube causes intussusception is not clearly understood. Harris[8] believed that the distended balloon acted like a polyp, which was also the opinion of Dunn and Shearburn[3] and Cantor and Reynolds.[5]

HYPERCORTISONISM IN PATIENTS WITH RHEUMATOID ARTHRITIS. —The clinical features of Cushing's syndrome which may be produced in patients receiving adrenal steroids are now familiar to most physicians. These features include fluid retention, moon face, abdominal striae, enlarged supraclavicular and cervicodorsal fat pads, hypertension, diabetes, osteoporosis, purpura, insomnia, hirsutism, excessive appetite, nervous tension, and other symptoms. It has been reported that from 66 to 75 per cent of all patients treated with adrenal steroids will develop one or more of these features. In addition to these usual features, however, many patients with rheumatoid arthritis under long term adrenal steroid therapy have been seen to develop certain unusual or "special" features of hypercortisonism. These special features comprise a syndrome which is characterized by musculoskeletal aching, fatigability, and cyclic mood changes. . . . Furthermore, these patients seem susceptible to so-called "mesenchymal reactions" which may simulate lupus erythematosus, a flare of rheumatoid arthritis, or periarteritis nodosa. Treatment of these special features of hypercortisonism consists in the steady, gradual reduction of dosage in small decrements according to the patient's reaction to the withdrawal.—J. W. Kemper, M.D., Hypercortisonism in Patients with Rheumatoid Arthritis, *Texas State Journal of Medicine,* December, 1958.

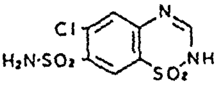
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based on available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary.*

Chlorothiazide (Diuril).—6-Chloro-7-sulfamyl-1,-2,4-benzothiadiazine-1,1-dioxide. — The structural formula of chlorothiazide may be represented as follows:



Actions and Uses.—Chlorothiazide, introduced commercially in 1958, is a potent, orally effective, nonmercurial diuretic agent. The drug is a potent inhibitor of the renal tubular reabsorption of sodium. In appropriate doses, it causes only a slight increase in excretion of bicarbonate and a considerable increase in the excretion of chloride. Potassium excretion is also increased but to a lesser extent than that of sodium or chloride. Under ordinary conditions of use, chlorothiazide does not alter urinary pH, nor does it cause significant changes in systemic acid-base balance. Its diuretic potency is greater than that of any other orally given nonmercurial diuretic presently available; it is only slightly less effective than parenterally administered mercurials. The mode of action of chlorothiazide in influencing the excretion of sodium and chloride has not been fully defined. Bicarbonate excretion is possible in the lower dose range because of a mild carbonic anhydrase inhibitory effect, but this effect is not responsible for the major excretion of sodium and chloride.

Chlorothiazide is rapidly and uniformly absorbed from the gastrointestinal tract. Its onset of action is rapid; diuretic effects are apparent within 2 hours after oral administration and persist for about 6 to 12 hours. Refractoriness to the drug is relatively uncommon even after prolonged periods of continuous administration.

Chlorothiazide is valuable as an adjunct in the management of congestive heart failure. The drug may be used for the initiation of diuresis as well as for the maintenance of the edema-free state in all types and degrees of severity of cardiac decompensation in which diuresis is required. As with any diuretic, patients with the most severe forms of the disease may be unresponsive to its action, particularly when the glomerular filtration rate is markedly reduced. Chlorothiazide is a satisfactory replacement for other orally given diuretics and can often be used in place of the parenterally administered organic mercurials. Its continued effectiveness makes it useful in many patients either who fail to respond or who have become refractory to other diuretics. Whereas therapy with chlorothiazide is not intended as a replacement for low-salt diets, administration of the drug makes it desirable to liberalize the salt intake in certain patients with congestive heart failure.

Chlorothiazide has been used with good results in the management of edema associated with nephrosis and certain types of nephritis. The drug may be of particular benefit to patients with nephrotic edema to whom corticotropin, glucocorticoids, and other agents which cause sodium retention are being administered concomitantly. If diuretic therapy is indicated in patients with edema caused by renal disease, chlorothiazide has an advantage over acetazolamide or ethoxzolamide in that it is most unlikely to precipitate a metabolic acidosis.

Chlorothiazide has been of value for the management of edema associated with liver disease, particularly portal cirrhosis. The drug has also been used for the treatment of toxemia and edema of pregnancy, for obesity or for premenstrual discomfort associated with fluid retention, and for the edema induced by such agents as corticotropin, adrenal cortical steroids, and certain estrogens.

In addition to its employment as a diuretic, chlorothiazide also is useful as an adjunct in the management of hypertension. When given alone, the drug generally has negligible or minimal lowering effects on the blood pressure. However, it is apparently capable of enhancing the effects of other antihypertensive agents such as Rauwolfia and Veratrum alkaloids, hydralazine, and the ganglionic blocking agents. It may also enhance the hypotensive effects of surgical sympathectomy. The mechanism of action of chlorothiazide in reducing high blood pressure has not been determined. The judicious use of chlorothiazide may make possible a sustained antihypertensive effect while allowing somewhat less rigid restrictions on dietary salt intake. When chlorothiazide is given in combination with other antihypertensive drugs, the dosage of the latter agents (particularly the ganglionic blocking agents and hydralazine) must be reduced markedly; this decreases or even eliminates certain of the more troublesome side-effects, including those resulting from parasympathetic ganglionic blockade.

Chlorothiazide is apparently well tolerated, and few serious immediate side-effects have been reported to date. It should be borne in mind, however, that the drug is an extremely potent compound in its influence on fluid and electrolyte excretion. It should not be given unless the patient can be regularly and carefully observed for the early signs of fluid and electrolyte imbalance and unless appropriate measures can be taken to prevent such imbalance or to correct it if it occurs.

In some patients, chlorothiazide may produce a hypochloremic alkalosis as the result of excessive excretion of chloride in relation to sodium and a concomitant rise in plasma bicarbonate levels. In these cases, the excretion of potassium is also likely to be excessive so that a hypokalemia is superimposed on the hypochloremic alkalosis. These electrolyte imbalances are more likely to occur during excessive or continued administration of the drug to patients who either fail to show a natriuretic response or, having shown an initial response, do not continue this response. Hypokalemia may result in increased sensitivity to the action of digitalis. Caution must therefore be employed to prevent hypokalemia when digitalis is administered. Changes in the dosage requirements for both digitalis and chlorothiazide must be anticipated. Patients with myocardial ischemia as a result of coronary artery disease may also have a predisposition to serious cardiac arrhythmias if hypokalemia occurs. Hypochloremic alkalosis may be treated by making up the chloride deficiency (ammonium chloride should not be given to patients with hepatic disease). Hypokalemia should be corrected by giving potassium chloride. Both electrolyte disturbances can usually be reversed by the temporary discontinuance of chlorothiazide.

Occasionally the so-called low-salt syndrome may complicate therapy with chlorothiazide in patients with severe congestive heart failure who are markedly edematous. This complication is most likely to occur when excessive amounts of the drug are administered at the same time that dietary salt intake is rigidly restricted. In some cases, it may be necessary to treat this condition with the cautious infusion of hypertonic sodium chloride solutions along with rigid restriction in water intake, even in the presence of intense thirst.

In patients with severe renal or hepatic impairment, as indicated by clinical and laboratory observations, diuretic therapy may be ineffective and even contraindicated.

In patients with advanced cirrhosis, chlorothiazide should be administered cautiously; it may be necessary in some instances to discontinue administration. It should be borne in mind that in certain patients with hepatic disease, particularly those who have a history of a previous episode of hepatic coma or precoma, electrolyte imbalance (among other factors) may precipitate hepatic coma. When chlorothiazide is used in patients with cirrhosis, it may be desirable to place them on a low-protein diet and to administer potassium glutamate by mouth, as well as a broad-spectrum, nonabsorbable antibiotic such as neomycin, to minimize the possibility of coma.

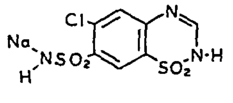
Rare side-reactions to chlorothiazide include nausea, epigastric discomfort, dizziness, weakness, and paresthesias. In occasional instances, a drug rash has been observed. The possibility of allergic reactions arising from sensitivity to the drug should be borne in mind.

Dosage.—Chlorothiazide is administered orally. Dosage must be highly individualized according to the response of the individual patient and the severity of the condition being treated. For diuretic effects, the usual dose for adults ranges from 500 mg. to 1 Gm. once or twice a day. A total daily dose of 1 Gm. or more is usually given in two divided doses. For antihypertensive effects in conjunction with the use of other antihypertensive drugs, the dosage of chlorothiazide ranges from as little as 250 mg. twice daily to 500 mg. three times a day.

Preparations: tablets 250 mg. and 500 mg.

Merck Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of chlorothiazide.

Chlorothiazide Sodium (Lyovac Diuril).—The sodium salt of 6-chloro-7-sulfamyl-1,2,4-benzothiadiazine-1,1-dioxide.—The structural formula of chlorothiazide sodium may be represented as follows:



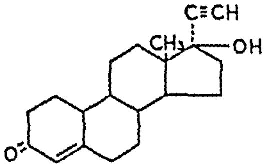
Actions and Uses.—The sodium salt of chlorothiazide, introduced commercially in 1958, has the same actions and uses as the parent substance except that it is more soluble and therefore suitable for parenteral injection. (See the monograph on chlorothiazide.)

Dosage.—Chlorothiazide sodium is administered intravenously. The lyophilized powder is reconstituted with a suitable volume of sterile diluent immediately prior to administration. The drug may be given as a concentrated solution by direct intravenous injection or may be infused slowly by intravenous drip. Dosage is the same as for chlorothiazide.

Preparations: powder (injection) 500 mg.

Merck Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of chlorothiazide sodium.

Norethindrone (Norlutin). — 17α-Ethinyl-19-nortestosterone.—The structural formula of norethindrone may be represented as follows:



Actions and Uses.—Norethindrone, sometimes referred to as norethisterone, is a highly potent, orally active, progestational agent which was introduced commercially in 1957. It produces the typical physiological and anatomic effects of progesterone and its derivatives, i. e., induction of a secretory endometrium, luteal changes in the vaginal epithelium, disappearance of cervical fern, increases in basal body temperature, and withdrawal bleeding from an estrogen-primed endometrium. When given from the 5th to the 25th day of the menstrual cycle, the drug is believed to inhibit ovulation. Continuous administration of norethindrone can also delay menstruation for prolonged periods, with only occasional instances of breakthrough bleeding. The pseudopregnancy thus induced is presumably an anovulatory amenorrhea. In terms of weight of drug required for progestational effects, norethindrone is one of the most potent agents known. Its onset and duration of action are about the same as with parenterally administered progesterone; if given for five days to amenorrheic women after estrogenic stimulation, the drug will generally induce withdrawal bleeding within 24 to 72 hours after its discontinuance. Animal experiments indicate that norethindrone has slight estrogenic effects; there is no evidence of androgenic activity. However, studies in animals are not adequate to estimate the extent to which observed histological changes may be due to the estrogenic activity of the drug. The drug is apparently not metabolized in the same manner as progesterone, since its administration does not cause an increase in the urinary excretion of 17-ketosteroids.

Norethindrone has been used in the treatment of primary and secondary amenorrhea. The drug will not induce secretory changes in the endometrium, with subsequent menstruation, unless there has been adequate estrogenic stimulation. Hence, in patients with inadequate endogenous estrogen production, as determined by vaginal cytology, estrogen priming is necessary. In women with menstrual irregularity or secondary amenorrhea due to inadequate corpus luteum activity, the monthly employment of norethindrone may help in reestablishing a normal cyclic pattern. This effect may be helpful in the management of patients with infertility problems, since it permits a more accurate prediction of the time of ovulation. Although the ultimate value of progestogens in the treatment of female infertility remains to be determined, agents such as norethindrone might theoretically be of value in establishing conditions conducive to pregnancy by reason of their inhibiting effect on the arborization of cervical mucus (which may act as a barrier to sperm penetration) and by preparing the endometrium for implantation of the ovum. Like other progestogens, norethindrone may be tried in the treatment of functional uterine bleeding, provided that genital malignancy has been ruled out and that curettage has established the diagnosis of benign endometrial hyperplasia.

Because it can induce a state of amenorrhea for as long as its daily administration is continued, norethindrone has been suggested as a means of temporary delay of the menstrual period for honeymoon, vacation, and athletic events. However, the use of a potent hormone to inhibit a normal physiological function, simply for patient convenience, should be discouraged. The menstrual-inhibiting property of the drug may, however, serve a useful purpose in alleviating the symptoms of endometriosis and causing a regression of endometrial implants.

Norethindrone, as well as other progestogens, has been tried in a more or less empirical manner for the treatment of threatened or habitual abortion. At present, there is a dearth of convincing evidence that any agent of this type can reduce the incidence of fetal loss. There is likewise insufficient evidence at hand to establish the proposed use of norethindrone for the treatment of premenstrual tension or dysmenorrhea.

The clinical use of norethindrone has not been associated with any appreciable toxicity. In occasional instances, mild nausea, lethargy, and spotting before the calculated onset or after termination of menstruation have been reported. In young animals, prolonged administration of large doses of the drug causes a decrease in food consumption, with a consequent depression in weight gain; however, anorexia and weight loss have not been a problem clinically. Prolonged therapy with norethindrone generally decreases libido, an effect that would negate its proposed use to delay menstruation during the honeymoon.

Dosage.—Norethindrone is administered orally. For amenorrhea, menstrual irregularity, functional uterine bleeding, and infertility, the usual dose is 10 to 20 mg. daily from the 5th to the 23rd day of the menstrual cycle. A five-day period is allowed for withdrawal bleeding to occur. Continuous daily doses of 20 to 30 mg. are usually sufficient to prevent menstruation. For the treatment of premenstrual tension and dysmenorrhea, the proposed dose is 10 mg. once or twice daily, beginning in the preovulatory phase and continuing to the 20th to the 23rd day of the cycle. Pending more evidence to show a beneficial effect, the proposed dosage for these latter purposes is considered experimental.

Preparations: tablets 5 mg.

Parke, Davis & Company cooperated by furnishing scientific data to aid in the evaluation of norethindrone.

ABUSE OF ANTIBIOTIC LOZENGES

ELSEWHERE IN this issue of THE JOURNAL (page 1235) a correspondent directs attention to the development of moniliasis of the soft palate and pharynx, sometimes fatal, after the use of antibiotic lozenges. Although antibiotic lozenges enjoy a degree of popularity in the local treatment of diseases of the throat, it is known that effective concentration of the contained medication cannot be maintained for long periods on the surface of the tonsils or pharynx because of the continual washing effect of saliva. There is no such response as rendering the throat sterile, or even antiseptic, except possibly for a short time.

In superficial infections of the throat, local administration of antibiotic and chemotherapeutic agents may be effective. However, their value diminishes if the micro-organisms have penetrated into the tissues. Actually, once micro-organisms have established themselves below the surface, and an abscess has formed, locally applied medicaments have little value. In acute streptococcic tonsillitis, for example, all of the offending organisms are not found on the surface of the tonsils—in reality, many of them lie deep in the tonsillar tissues. Under such circumstances, the value of lozenges, troches, pastilles, and medicated chewing gum is dubious. Deeply seated bacteria are best approached systemically. It is dangerous to rely on local medication alone in the treatment of severe infections of the throat.[1]

Inadequate dosage and indiscriminate usage of topical antibiotic and sulfonamide compounds in the treatment of infectious diseases of the throat can breed resistant bacterial strains. Their promiscuous use is unwarranted in trivial infections; moreover, their use is limited from time to time by the development of allergic reactions, by the sensitiveness of patients to these agents, by the acquisition of antibiotic-resistance and sulfonamide-resistance states, and by their ability to mask symptoms occasionally. Finally, stomatitis has been traced to various antibiotics and sulfonamides present in a variety of lozenges, troches, pastilles, and medicated chewing gum.

THE PHYSICIAN'S ROLE IN SAFE DRIVING

In this issue of THE JOURNAL, *page 1195, is a* report prepared by the Committee on Medical Aspects of Automobile Injuries and Deaths which will be of value to physicians called on to advise whether or not an individual is capable of driving a motor vehicle safely.

It can easily be determined if the individual meets the physical standards for driver licensing established by the state licensing authority. These standards lend themselves to precise measurement. Not easily measured and not well understood in the production of automobile accidents are factors such as poor judgment, emotional disturbances, and faulty attitudes.

Injuries suffered in automobile accidents are an important health problem in the United States. About 37,000 persons were killed in automobile accidents in 1958 and about 5 million were injured seriously enough to require medical attendance or restriction of their activity for one day or longer.

Most automobile accidents occur because of human failures. Many drivers are physically, mentally, emotionally, or physiologically impaired, sometimes only temporarily, sometimes permanently. The evaluation of impairment in relation to safe driving ability is best done by physicians. It is the purpose of the guide, which this committee prepared after some two years of study, to assist the physician in his evaluation.

The number of registered vehicles, the number of licensed drivers, and the number of miles driven are steadily increasing. Exposure to motor vehicles occurs daily in the lives of the majority of Americans. The many groups working in the accident prevention field are trying to see that this exposure does not result in injury. Physicians can make a great contribution in automobile accident prevention by determining the fitness of drivers to operate motor vehicles.

Introduction

Traffic accidents killed about 37,000 individuals in 1958 and injured about 1,350,000, according to the National Safety Council. These data were developed from the reports of official agencies. The data refer to the number of injuries causing disability beyond the day of the accident. The U. S. Public Health Service has estimated that there are about 4,700,000 injuries annually in automobile accidents. This estimate was based on the National Health Survey of 1957-1958 which derived its data from household interviews. Persons with injuries involving one or more days of restricted activity or medical attendance were included. On the basis of the latter figure it has been predicted that 1 person in every 10 in this country will be injured or killed in a motor vehicle accident within the next four years. This constitutes one of the nation's largest unsolved health hazards.

It is the purpose of this guide to call attention to the areas in which the medical profession may be of help in combating this serious health problem. This guide has been prepared to assist physicians in examining patients and advising them on their ability to operate a motor vehicle safely. Physical, mental, and emotional states or disabilities likely to impair driving ability are specifically enumerated along with the problems of temporary incapacities from medicaments and alcohol.

The physical and mental demands of the task of driving vary greatly with the type of vehicle and the type of driving. For this report, three types of vehicles have been considered—the private motor vehicle, the commercial vehicle, and the passenger transport vehicle. The driver of the commercial or passenger transport vehicle cannot usually choose the hours he will drive nor the route he will take. The driver of the private vehicle may, in many cases, select both the time of his travel and the route. The driver of the commercial or passenger transport vehicle will spend more hours daily in driving than most drivers of private vehicles. There is little similarity between the demands on the resources of the individual who drives half a mile to the store on a rural road with no intersections and the individual who drives in rush hour traffic in a metropolitan area. The physician should keep these matters in mind when advising his patients on their fitness to drive.

Prepared by the Committee on Medical Aspects of Automobile Injuries and Deaths, American Medical Association. Committee members are Fletcher D. Woodward, M.D., Chairman, Charlottesville, Va.; Horace E. Campbell, M.D., Vice-chairman, Denver, Colo.; Jacob Kulowski, M.D., St. Joseph, Mo.; Harold M. Brandaleone, M.D., New York; John R. Rodger, M.D., Bellaire, Mich.; Seward E. Miller, M.D., Ann Arbor, Mich.; Ross A. McFarland, Ph.D., Boston; James L. Goddard, M.D., Washington, D. C.; and Howard N. Schulz, Secretary, Chicago.

All states but one have laws concerning the physical requirements for driver licensing. Every physician should be familiar with the laws, and his advice to patients must be consistent with the laws of the state in which his patient is licensed.

Human failure overshadows all other factors in the production of highway accidents. The human mechanism must be in good condition to cope with the split second timing needed to maneuver responsive high speed motor vehicles. There is no doubt that poor judgment, impaired reaction time, faulty attitudes, emotional disturbances, and physical disabilities, including impairment of the sensory organs, are basically responsible for most accidents. Thus, the key to ultimate success in automobile accident prevention lies in the driver—his intelligence, his sense of personal and social responsibility, his reactions to various stimuli in normal conditions and under stress, and his driving ability in good health and in illness.

The physician is qualified by training to ascertain the physical, mental, emotional, or physiological impairments of an individual. Moreover, he is in a good position to evaluate these impairments in relation to safe driving ability. Obviously, it is not always easy to arrive at a decision in these cases. Variations in severity of illness or impairment, variations in individual reactions and adjustment, and variations in individual response to medicaments are significant factors in evaluating each case. However, even in the realm of behavior patterns, the physician is in an ideal position to do effective counseling by translating scientific data into terms of lay understanding. Few patients realize the small amounts of alcohol required to impair dangerously their driving ability or that alcohol is involved in about 50% of automobile accidents with fatalities; nor does the slightly inebriated driver realize that he materially increases his likelihood of a serious accident.

A conscientious individual may inquire, "Doctor, is it all right for me to drive an automobile in my condition?" This situation usually is conducive to a receptive patient attitude if perchance the advice may be "bad news." Frequently, it may be necessary for an equally conscientious physician, recognizing his responsibility for the safety of his patient and the public, to caution the patient against driving for a certain period of time or even permanently, unhappy as this may make the patient. Many of these conditions have been graphically described for the lay public in a previous publication of this Committee, entitled "Are You Fit to Drive?" Physicians should find this descriptive pamphlet (available from the Association of Casualty and Surety Companies, 60 John St., New York 38) helpful in dealing with adamant patients.

When physicians discover any conditions in their patients which might make it inadvisable for them to drive a motor vehicle, they should advise the patients to report the condition on the next application for renewal of the driver's license. This is for the patient's own protection. If this information is not reported on the application and the applicant subsequently becomes involved in an accident to which the condition either directly or indirectly might be a contributing cause, in many states the insurance company may legally refuse liability.

This guide is devoted to the physician's role in helping prevent motor vehicle accidents through appropriate advice and treatment to patients. However, it is recognized that many accidents will continue to occur. Therefore, the Committee also is interested in preventing, as much as possible, personal injury to the occupants of vehicles involved in accidents.

The elimination of many road hazards by improved highway design and construction is proceeding at a fast pace. Also, there has been great improvement in the maneuverability, responsiveness, and speed of acceleration and deceleration of automobiles. In the construction of the motor vehicle lies a great opportunity for the prevention of serious injury to the occupants when accidents do occur. It is possible to design, build, and equip an automobile so that injury or death will occur only in the more extreme crashes. In a car so designed and equipped, personal injuries and deaths would be minimized although accidents continue to occur. It is obviously simpler mechanically to change the design of automobiles to protect frail man than it is biologically to change the design of man to resist traumas—therefore the present urgency for automotive engineers to lend their great talents to this end. Of course, the public needs to understand, accept, and be willing to pay for such design and mechanical changes.

It is probable that the next decade will see a greatly increased emphasis upon more stringent physical standards for driver licensing. It is believed that more and more patients will turn to their physicians for advice and assistance in this regard. In a subsequent publication, this Committee will recommend physical standards for driver licensing and for the guidance of licensing authorities and physicians.

Medicine

Fever, fatigue, metabolic diseases, effects from various drugs, and carbon monoxide poisoning are among the medical conditions adversely affecting driving ability. Cardiovascular disease and alcohol are dealt with in separate sections. Physicians should be familiar with the entities here described.

Assessing Safe Driving Ability.—In general, the individual should be assessed medically to determine the answers to the following questions: 1. Has the patient the physical and mental ability to manipulate the controls? 2. Is the patient likely to suffer excessive fatigue that will impair his driving ability? 3. Does the patient have the required vision and hearing for safe driving? 4. Has the patient any physical or mental disorder likely to cause confusion or a sudden loss of consciousness while driving? 5. Is the patient likely to suffer a temporary impairment of mental, physical, or functional capacity due to alcohol, drugs, infections, or medical treatment, etc., making it unsafe for him to drive? 6. Does the patient have good emotional control or has he signs of antisocial behavior or an emotional disturbance making it unsafe for him to drive?

Metabolic Diseases.—Disturbances in function of the endocrine glands cause many varied symptoms from generalized asthenia, muscle weakness, and spasm or tetany to sudden episodes of vertigo or unconsciousness. Individuals so afflicted should be advised not to drive a motor vehicle until these symptoms have been controlled by appropriate therapy. The more important conditions likely to impair the driving ability of such patients are discussed briefly:

Diabetes Mellitus: Patients suffering from diabetes mellitus of a degree that can be controlled adequately by diet alone may drive any type motor vehicle. Also older individuals with mild diabetes controlled by diet and a sulfonylurea type drug who experience no reactions from the drug may drive any type motor vehicle. If insulin is required and the diabetes well controlled, the individual may drive a private vehicle. However, he should be advised not to drive a commercial or passenger transport vehicle because of the possibility of a sudden attack of hypoglycemia. The uncontrolled diabetic should be advised not to drive any type motor vehicle because of the development of disabling complications. On the other hand, an individual with true renal glycosuria may safely drive any type motor vehicle.

Hyperinsulin States: Individuals suffering from recurring spontaneous attacks of hypoglycemia, pancreatic islet cell adenoma, or other organic or functional causes should be advised not to drive any type of motor vehicle while subject to an attack of faintness, giddiness, or unconsciousness. Patients with mild cases who never develop unconsciousness or disabling symptoms of faintness may drive a private vehicle but should be advised not to drive a commercial or passenger transport vehicle.

Thyroid Disease: In addition to having tachycardia, exophthalmos, and tremor, patients with hyperthyroidism are prone to emotional disturbances, anxiety, and even psychotic symptoms. Therefore, individuals with thyrotoxicosis should be advised not to drive any type of motor vehicle until the disabling symptoms are well controlled. In addition, individuals suffering from an enlarged thyroid gland with pressure symptoms should be advised not to drive a commercial or passenger transport vehicle, although usually they can drive a private vehicle. Individuals with marked myxedema or cretinism should be advised not to drive a motor vehicle.

Hyperparathyroidism and Hypoparathyroidism: Individuals suffering from hyperparathyroidism with muscular weakness and hypotonia should be advised not to drive a motor vehicle. When symptoms are mild or well controlled by therapy, these individuals may drive private motor vehicles but not commercial or passenger transport vehicles.

Individuals suffering from acute hypoparathyroidism with increased neuromuscular excitability, cramps, spasm, and generalized tetany should be advised not to drive a motor vehicle. Chronic hypoparathyroidism varies greatly in its manifestations and severity. Persons with mild cases without tetany may drive private motor vehicles but should be advised not to drive commercial or passenger transport vehicles. However, with the development of tetany, muscular weakness, or ease of fatigue, these patients should be advised not to drive any motor vehicle.

Posterior Pituitary Insufficiency: Individuals suffering from diabetes insipidus should be advised not to drive a commercial or passenger transport vehicle. Under careful medical supervision they may drive private motor vehicles unless visual disturbances or other disabling central nervous system symptoms develop.

Anterior Pituitary Insufficiency: The severe carbohydrate deficiency and spontaneous hypoglycemic episodes that characterize hypopituitary cachexia (Simmond's disease) make it mandatory that these individuals should not drive any motor vehicle. Under close medical supervision, those persons making a good recovery and without hypoglycemic episodes may drive a private motor vehicle but should be advised not to drive a commercial or passenger transport vehicle.

Acromegaly: With the development of muscular weakness and pain, ease of fatigue, cardiac enlargement, and intractable headaches, patients with acromegaly, or gigantism, should be advised not to drive any motor vehicle. Moreover, about 50% of these patients develop visual disturbances which also make it unsafe for them to drive.

Adrenal Cortical Hyperfunction: Patients with adrenal cortical hyperfunction (Cushing's disease), who develop muscular weakness and osteoporosis, should be advised not to drive a motor vehicle. Good recovery after appropriate therapy enables these individuals again to drive a private vehicle. However, they should be advised not to drive a commercial or passenger transport vehicle.

Adrenal Cortical Hypofunction: Patients with well-developed cases of adrenal cortical hypofunction (Addison's disease), particularly those with asthenia and/or persistent low blood pressure, should be advised not to drive a motor vehicle.

Persons with mild cases or those whose symptoms of asthenia and low blood pressure are well controlled by therapy may drive a private vehicle but should be advised not to drive a commercial or passenger transport vehicle.

Hyperfunction of Adrenal Medulla: Hyperfunction of adrenal medulla occurs with the development of pheochromocytoma tumor which clinically is characterized by attacks of headache, dizziness, weakness, and blurring of vision with a rapid pulse and elevated blood pressure. Until completely free of these attacks by removal of the tumor, such individuals should be advised not to drive a motor vehicle.

Drugs.—Numerous drugs, either self-administered or taken at the direction of a physician, produce reactions in some individuals impairing that individual's ability to drive a motor vehicle. The degree of impairment varies tremendously, depending on the severity and type of reaction. Physicians administering drugs likely to produce reactions impairing sensory, mental, or physical functions have a clear responsibility to fully inform their patients concerning this matter, especially as it effects their ability to drive a motor vehicle.

In addition, some patients experience unusual reactions to drugs that ordinarily do not produce disabling symptoms. Physicians must ever be alert to this possibility. Should unusual reactions, allergic or otherwise, occur which impair sensory, mental, or physical functions making it unsafe to drive, the physician must advise the patient not to drive a motor vehicle until the disabling symptoms have been eliminated. The more important groups of drugs likely to impair driving ability are discussed briefly.

Central Nervous System Depressants: The drowsiness induced by analgesic drugs sufficiently impairs driving ability so that patients with such drowsiness should be advised not to drive a motor vehicle. In addition, morphine, its derivatives, and the synthetic narcotics, such as meperidine (Demerol) hydrochloride, cause varying amounts of euphoria, inability to concentrate, apathy, dimness of vision, and rapid flow of uncontrolled thought. Patients under the influence of these drugs should be advised not to drive a motor vehicle.

Hypnotics, Sedatives, and Anesthetics: Hypnotics, sedatives, and anesthetics not only depress central nervous system activity, producing drowsiness and sleep, but also they may produce motor and sensory changes. No doubt small doses of some of these drugs, quieting a highly excited and "jittery" patient, may actually temporarily improve his driving ability. However, this is not the usual circumstance. Therefore, it is best to advise patients taking hypnotic doses of these drugs not to drive a motor vehicle. Patients receiving mild sedation who experience no drowsiness may drive. Of course, a barbiturate addict is incapable of driving a motor vehicle safely. Patients receiving barbiturates and local anesthetics for minor surgery should be advised not to drive.

Tranquilizing Drugs: During the initial period of administration of tranquilizing drugs, such as meprobromate, chlorpromazine, and reserpine, some drowsiness is frequently experienced. Also, with large doses, the accompanying hypotension may occasionally produce short episodes of faintness or giddiness. Therefore, during the initial phase of dosage adjustment, the patient should be advised not to drive a motor vehicle if he is experiencing drowsiness or faintness. At all times these patients should be carefully observed for symptoms of drowsiness or faintness. Patients stabilized on a maintenance dosage of these drugs, who are without symptoms of drowsiness or episodes of faintness, may drive a private motor vehicle but should be advised not to drive a commercial or passenger transport vehicle.

Central Nervous System Stimulants: Although central nervous system stimulants, such as amphetamines, temporarily increase alertness and efficiency, large doses in some individuals may produce headache, dizziness, agitation, irritability, and a decreased ability to concentrate. In all individuals, a period of fatigue and depression follows the initial stimulation. In rare instances an individual may take one of these drugs to prolong the period of alert driving. The dosage should not be more than 5 or 10 mg. and without repetition that day. Drugs of this type should be used only on advice of a physician.

Antihistamines and Drugs Preventing Motion Sickness: There is great individual difference in reaction to antihistamines and drugs preventing motion sickness, with dizziness or drowsiness occurring fairly frequently. Moreover, it is unpredictable in which individuals these symptoms will occur. Patients under medication with these drugs should be advised not to drive a motor vehicle until it has been established by prior trial that they do not experience dizziness or drowsiness.

Anti-infective Agents: In full and prolonged dosage with anti-infective agents, there may occur undesirable reactions of nausea, loss of sense of balance with dizziness, ringing in the ears, and deafness. A patient developing such symptoms should be advised not to drive a motor vehicle. Patients receiving over 1 Gm. of streptomycin daily should be watched carefully for the development of adverse symptoms.

Sulfonamides: Patients receiving sulfonamides should be warned that if they develop any drowsiness or dizziness they at once should cease driving a motor vehicle.

Hallucinogens: Hallucinogens, such as marijuana, have singular abilities for changing normal emotional reactions even causing individuals to become oblivious or indifferent to their surroundings. Individuals under the influence of these drugs should be advised not to drive a motor vehicle.

Fatigue.—Fatigued, drowsy, and sleepy drivers are responsible for many accidents. They are unable to make split second decisions, reaction time is slowed, and there is loss of peripheral vision and attention. In addition, many individuals are victims of "highway hypnosis," or hallucinations, some after only a few miles of monotonous superhighway driving. Among commercial and passenger transport drivers, most accidents occur within a few hours after the start of a trip. This is due, in part, to their off-duty activities. Thus, all drivers should be cautioned against driving after inadequate rest. Moreover, persons who periodically develop "highway fatigue" should be advised against driving a commercial or passenger transport vehicle.

Because of the development of fatigue, patients should be advised not to drive over eight hours in one day. The vehicle should not be kept too warm, and on continuous drives the operator should be advised to stop, get out, and walk around every two or three hours. In some instances, despite partial fatigue, a driver must proceed. Caffeine in the form of coffee, cola drinks, or tablets will help some individuals. In the rare case where prolonged driving is necessary, a central nervous system stimulant such as benzedrine may be used, but physicians should be very cautious in prescribing stimulants for this use.

Fever and Infectious Diseases.—Patients in the fever stage of an infectious disease should be advised not to drive because of decreased attention and impaired judgment and reaction time.

Carbon Monoxide.—The adverse effect of carbon monoxide, from exhausts and from smoking, on driving ability is in decreasing the visual sensitivity of the eye in areas of low illumination. The relative oxygen deficiency from smoking three cigarettes is equal to that of traveling at a 7,500-ft. altitude. Since adequate ventilation does not take care of chain smokers who inhale, drivers should be advised to refrain from frequent smoking prior to and during periods of night driving or at high altitudes.

Cardiovascular Disease

The examination of the cardiovascular system in determining a patient's ability to drive a private, commercial, or passenger transport vehicle should consist of a complete cardiac history and physical examination. The history should establish presence or absence of edema, orthopnea, cyanosis, dyspnea, and substernal or precordial pain. Also, a history of rheumatic fever, congenital deformities, thyroid disease, syphilis, hypertension, and anemia should be sought.

In order that the cardiovascular system be properly evaluated, the entire body must be examined, including the fundi, lungs, abdomen, and extremities. The physical examination, including palpation, percussion, and auscultation of the heart, should determine if venous congestion, cardiac enlargement, or valvular disease is present. The heart rate, rhythm, and level of blood pressure should also be ascertained.

Urinalysis, blood count, sedimentation rate, and serologic tests for syphilis should be done. Cardiac fluoroscopy, chest x-ray, and an electrocardiogram complete the examination of the cardiovascular system. In evaluating the cardiac status of an individual, it is important to ascertain the presence of cardiovascular disease and then its status according to cause, anatomic defects, physiological abnormalities, and functional capacity.

The lack of conclusive statistical data concerning the role of each cardiac condition as a potential driving hazard is recognized. However, on the basis of knowledge of pathological physiology and the clinical course of these cardiac conditions, it is believed that a medical opinion can be formulated as to the potential driving hazard. These hazards include sudden death, lapse of consciousness, and pain sufficient to cause loss of control of the car.

Etiological and Anatomic Classification.—The principal disabling cardiac conditions and their significance in relation to the safe operation of a motor vehicle are portrayed. It is hoped that this material, presented on (1) an etiological and anatomic basis and (2) a physiological and functional capacity basis, may serve as a basic guide for physicians in their evaluation of such patients.

Rheumatic Fever: Any evidence of active rheumatic fever calls for marked restriction of activity. Therefore, such a patient should be advised not to operate a motor vehicle.

Rheumatic Heart Disease: Appraisal must be made of the extent of damage in connection with valvular deformity, derangements of rhythm, progressive cardiac enlargement, and myocardial insufficiency. Aortic stenosis, when marked, is prone to lead to angina pectoris, syncope, or sudden death. Patients with significant aortic stenosis should be advised not to operate a motor vehicle. Patients with lesser degrees of aortic stenosis without symptoms of angina or syncope should be advised not to operate passenger transport vehicles but may operate a commercial or a private motor vehicle. Patients with aortic insufficiency and left ventricular failure with dyspnea or paroxysmal nocturnal dyspnea should be advised not to operate a motor vehicle. Patients with lesser degrees of aortic insufficiency without dyspnea should be advised not to operate passenger transport vehicles but may operate a commercial or private motor vehicle.

Patients with myocardial insufficiency due to mitral stenosis or insufficiency should be advised not to operate either commercial or passenger transport vehicles but may continue to operate a private vehicle when the myocardial failure is well controlled by therapy with only minimal dyspnea on exertion. Valvular deformity due to rheumatic fever involving the tricuspid and pulmonic valves is less common. Patients with evidence of right-sided heart failure should be advised not to operate either commercial or passenger transport vehicles. If the heart failure is controlled by therapy, the patient may operate a private motor vehicle. A superimposed subacute bacterial endocarditis necessitates immediate treatment and abstinence from operating any motor vehicle.

Disturbances of rhythm are frequent complications of rheumatic heart disease. Uncontrolled auricular tachycardia, flutter, or fibrillation with a rapid ventricular rate is apt to be associated with a diminished cardiac output, severely incapacitating the patients, and therefore they should not operate any motor vehicle. However, when well-controlled by therapy, such patients may operate a motor vehicle. Because of the work load and stress on the heart and the danger of embolization, patients having auricular fibrillation should be advised not to operate commercial or passenger transport vehicles.

Hypertensive Cardiovascular Disease: The upper limit of normal blood pressure is considered to be 150-160/90 mm. Hg. Many patients have labile blood pressures and particularly when seen on the first examination in the office may show levels of pressure above this. If the blood pressure is consistently above 150-160/90 mm. Hg., fixed hypertension must be considered to be present and its cause should be ascertained. Hypertension in itself is not disabling for the safe operation of a motor vehicle, but the complications arising from hypertension, i. e., damage to brain, eyes, heart, or kidneys, may well prove to be so disabling. When the complications of hypertension are limited to the optic fundi, the degree of impairment of driving ability should be evaluated solely on the basis of loss of vision. If there is any evidence that the hypertension has caused cardiac damage resulting in congestive heart failure or angina pectoris, such patients should be advised not to operate a motor vehicle, unless the congestive failure or angina is well controlled by therapy.

Arteriosclerotic Heart Disease: Sclerosis of the coronary vessels results in diminution of blood flow, particularly during exertion, with insufficient nourishment of the myocardium, resulting in angina pectoris. If the original attacks are mild, infrequent, and controlled with therapy, such patients may still drive private motor vehicles but not commercial or passenger transport vehicles.

More prolonged episodes of inadequate myocardial nourishment and substernal pain are termed coronary insufficiency. Arteriosclerotic heart disease may also result in various abnormalities of conduction with varying degrees of heart block, ventricular premature contractions, or arrhythemias. Patients with such symptoms well controlled by therapy may drive private motor vehicles. They should not operate commercial or passenger transport vehicles.

Syphilitic Heart Disease: Patients with syphilitic aortitis having syncope, congestive heart failure, or angina pectoris should be advised not to operate a motor vehicle. If syphilitic aortitis has led to the development of aortic insufficiency, then careful evaluation should be made of the patient concerning the presence of angina pectoris, syncopal attacks, left ventricular enlargement, or congestive heart failure. If any of these have occurred, the patient should not operate commercial or passenger transport vehicles, and, unless the symptoms are well controlled by therapy, the patient should be advised not to operate a private motor vehicle.

Bacterial Endocarditis or Endarteritis: Patients with acute bacterial endocarditis under vigorous treatment are so ill and their activities so restricted that they should not consider operating a motor vehicle. In addition, patients with subacute bacterial endocarditis, because of the danger of embolization to the brain, should be advised not to operate a motor vehicle.

Metabolic Heart Diseases: Patient with thyrotoxic or beriberi heart disease or with severe anemia with impairment of oxygenation of the myocardium or myxedema heart disease, when severely ill, are so incapacitated that they should be advised not to operate a motor vehicle.

Congenital Heart Disease: Some cases of congenital heart disease, such as patent ductus arteriosus, coarctation of the aorta, tetrology of Fallot, and septal defects are amenable to surgical treatment. If signs of myocardial insufficiency are present, such patients should be advised not to operate a commercial or passenger transport vehicle but may operate a private vehicle unless symptoms of myocardial insufficiency are pronounced. Asymptomatic congenital heart lesions are of no significance.

Cor Pulmonale: Patients with right-sided heart failure secondary to disease of the lungs with venous distention, enlargement of the liver, ascites, and edema should be advised not to operate commercial or passenger transport vehicles. However, if the symptoms of right ventricular failure are mild and well controlled by therapy, such patients may operate private motor vehicles.

Myocarditis: Any evidence of active myocarditis due to rheumatic fever, diphtheria, or other causes requires bed rest, and such patients should therefore be advised not to operate motor vehicles.

Arterial Aneurysms and Arteriovenous Fistulas: Any patient having an arterial aneurysm, because of the danger of its rupture, should be advised not to operate any motor vehicle. Arteriovenous fistulas may result in heart failure which, if severe, will be a contraindication to the operation of any motor vehicle. Both conditions may be amenable to surgical treatment.

Diseases of the Pericardium: In the acute phase of pericarditis, patients under therapy are unable to operate any motor vehicle. Benign infectious pericarditis of unknown cause does not constitute a contraindication to the operation of a motor vehicle, once the acute phase has subsided.

Chronic Constrictive Pericarditis: Patients having severe cases with venous distention, enlargement of the liver, and peripheral edema should be advised not to operate a commercial or passenger transport vehicle. If the condition is well controlled by therapy, patients with chronic constrictive pericarditis may operate a private motor vehicle safely.

Cerebral Vascular Disease: Patients with inadequate blood flow to the brain because of artherosclerosis of the cerebral vessels are apt to have attacks of syncope or dizziness and should be advised not to operate a motor vehicle. If there have been cerebral hemorrhages, thrombosis, infarctions, transient cerebral vascular spasms, or small areas of cerebral softening with resulting changes in personality, alertness, ability to make decisions, or if there has been actual loss of motor or sensory power, or coordination, such patients should be advised not to operate a motor vehicle. If the resulting changes in function are minimal, with little or no disability, it may be possible for these individuals to drive a private motor vehicle.

Diseases of the Veins: Patients with active thrombophlebitis or a previous thrombophlebitis with resulting edema of the extremities and impairment of use should be advised not to operate a commercial or passenger transport vehicle, and, if sufficient disability exists, they should be advised not to drive a private motor vehicle. Patients with active phlebothrombosis should be advised not to drive a motor vehicle because of the danger of embolization with pulmonary infarction.

Physiological Abnormalities.—Physiological abnormalities and disturbances of functional capacity now will be considered in relation to safe driving.

Cardiac Enlargement: Enlargement of either the right or left ventricle should not in itself be considered a contraindication to the operation of a motor vehicle, but such enlargement does point to the presence of organic heart disease which deserves evaluation.

Diminished Cardiac Reserve: Minor degrees of impairment of function of the myocardium will result in dyspnea on exertion. If this is minimal it should not be a contraindication to the operation of a motor vehicle. If myocardial insufficiency is more marked so that dyspnea prevents the performance of the usual duties involved in the operation of a commercial motor vehicle or is likely to prevent proper performance under emergency conditions, then such patients should be advised not to operate commercial or passenger transport vehicles. If the congestive heart failure is well controlled by therapy, these patients may operate a private motor vehicle. These same considerations apply to either hepatomegaly or peripheral edema resulting from myocardial insufficiency.

Arrhythmias and Conduction Disturbances: Auricular premature beats are of little consequence and do not preclude the operation of motor vehicles. Patients with paroxysmal auricular tachycardia, flutter, or fibrillation with myocardial insufficiency should be advised not to operate a commercial or passenger transport vehicle. If such attacks are well controlled by therapy, then the patients may operate any motor vehicle. Auricular fibrillation of a chronic nature provides the risk of embolization from the auricles, and such patients therefore should not operate commercial or passenger transport vehicles.

Ventricular arrhythmias other than occasional ventricular extrasystoles are usually associated with serious heart disease and frequently are the cause of sudden death. Such patients should be advised not to drive commercial or passenger transport vehicles but may drive private vehicles.

Auriculoventricular block, if of minor degree, is of no significance. Patients with prolonged degrees of atrioventricular block or complete atrioventricular block, if associated with convulsive disorders due to Stokes-Adams syndrome, should be advised not to operate a motor vehicle. If these attacks are controlled by therapy, such patients may operate private motor vehicles.

Pain due to Coronary Arterial Insufficiency: Angina pectoris, coronary insufficiency, and myocardial infarction are all indications of impaired blood supply to the myocardium. Such patients should be advised not to operate commercial or passenger transport vehicles. If angina pectoris is mild and controlled by therapy, then such patients may operate their private motor vehicles. The same is true for patients recovering from a myocardial infarction.

Pain due to Pulmonary Hypertension: The significance of pain due to pulmonary hypertension is primarily in differentiating it from pain due to coronary arterial insufficiency. Patients with pulmonary hypertension are not as prone to sudden death and therefore may, if the degree of pain is not too severe or when well controlled by therapy, operate any type of motor vehicle.

Hypertension: The presence of an elevated blood pressure, due to any cause, above 150-160/90 mm. Hg in itself should not be considered as a contraindication to the operation of a motor vehicle. Complications of hypertension do result in disability contraindicating operation of a motor vehicle. Usually persistent hypertension above 180/100 mm. Hg is accompanied by complications that may be dangerous to driving. Such patients must be examined very carefully to make sure that there has been no involvement of the eyes, brain, heart, or kidney likely to prove disabling for the safe operation of commercial or passenger transport vehicles. When such severe impairment or disability exists, the patient should be advised not to operate private motor vehicles.

Hypotension: Hypotension in itself is not a contraindication to the operation of a motor vehicle. If hypotension results in attacks of syncope, such patients should be advised not to operate a motor vehicle. When these attacks are controlled by therapy, patients may operate a private motor vehicle.

Carotid Sinus Sensitivity: Individuals with carotid sensitivity who experience attacks of syncope should not drive a motor vehicle.

Ophthalmology

Adequate vision is essential for the proper and safe operation of a motor vehicle. Visual potentials can be ascertained by using available vision testing instruments.

Licensing authorities have established visual acuity requirements ranging from 20/30 to 20/70. Two states have no specific visual requirements. Every physician should familiarize himself with the visual requirements of his state's licensing authority.

The patient's perception of what he sees is of great importance. As yet, however, there is no practical way of testing for faulty perception. It is important for drivers to have their vision periodically evaluated, particularly those with significant progressive visual deterioration.

Visual Acuity.—At present we believe that patients whose corrected vision, tested under standard conditions, is 20/40 or better may be advised that this vision is adequate for the task of operating a private vehicle. Those with vision less than 20/40 should be referred to an ophthalmologist to ascertain if vision can be improved. Patients with less than 20/70 corrected vision in the better eye should be advised not to drive.

At present there is no uniformity of opinion regarding the safe driving ability of individuals with visual acuity between 20/40 and 20/70. Furthermore, there are no scientific data available which permit the establishment of fixed standards.

The physician, in serving the best interests of these patients, should consider the conditions under which each patient drives and the vision the patient possesses. He is then in a position to advise the patient whether or not he should drive in congested traffic, in hazardous road conditions, at high speed, or at night. It is hoped that continuing research in this field will lead to a more exact basis upon which to advise patients.

The one-eyed or aphakic driver presents special problems. Many individuals in this category acquire judgment of distance and develop the ability to drive safely. Those individuals who have not acquired this judgment should be advised not to drive and to consult an ophthalmologist.

Regulations for licensing drivers of commercial and passenger transport vehicles usually require higher visual acuity than most licensing agencies require for drivers of private vehicles.

Visual Fields.—Second in importance to visual acuity are visual fields, i. e., form fields. These are obviously important for safe driving, for a driver must of necessity possess some depth and lateral perspective in the horizontal meridian in order to pass approaching vehicles safely as well as being aware of approaching vehicles or pedestrians from the side.

Patients with visual form fields of 140 degrees or more may be advised that this field is sufficient for the task of operating a motor vehicle. Patients with form fields less than 110 degrees should be advised not to drive. The patient with a field between these limits must be evaluated on the basis of the conditions under which he drives and the amount of lateral vision he possesses.

Individuals with markedly constricted fields, such as those suffering from severe glaucoma or retinitis pigmentosa with peripheral blindness, are unfit for safe driving and should be advised not to drive.

Ocular Muscle Imbalance.—The accident potential of ocular muscle imbalance is indirect through causing driver fatigue. However, when diplopia occurs, accidents are directly attributable to the diplopia. Therefore, all patients with uncontrolled diplopia should be advised not to drive a motor vehicle.

Color Blindness.—Color blindness has in the past been considered to be a potential cause of highway accidents. At the present time, however, traffic lights have been standardized, and, except in cases of those engaged in interstate or heavy transport, it is doubtful if color blindness or deficiency is of any great consequence.

Dark Adaptation.—Dark adaptation and susceptibility to glare are of importance in night driving, but at the present time no valid data are available as to their importance in the causation of highway accidents. Of course, dark glasses should not be worn for night driving and windshield tinting should be limited to the upper one-third.

Depth Perception.—Tests for depth perception are inadequate at this time. The road test is still best and is practical.

Otolaryngology

Deafness and dizziness or vertigo due to internal or middle ear disturbances are the principal otological symptoms of significance in the safe operation of a motor vehicle.

Although deafness is a handicap in the safe operation of a motor vehicle, usually it is compensated for quite well. The deaf driver, being fully conscious of his disability, tends to be cautious and fully alert at all times. Moreover, the use of an outside rear view mirror is of great value. The wearing of hearing aids has not proved practical in noisy commercial or passenger transport vehicles. However, in the operation of private vehicles, patients who successfully wear hearing aids frequently find the hearing aid most useful. Thus, much depends on the vehicle, road noise, the patient, and his type of deafness. Although deafness is disqualifying in the operation of a passenger transport vehicle, this is not necessarily so for the operation of a commercial or private vehicle. However, some licensing authorities and the Interstate Commerce Commission have specific regulations in this matter which the physician will need to consult when patients need advice in this area. This information may be secured from the state licensing authority.

Patients subject to attack of Ménière's syndrome or sudden dizziness, no matter what the cause, should be advised not to operate a motor vehicle until proper treatment has controlled such attacks, when he may resume driving a private vehicle but not a commercial or passenger transport vehicle. The character of the attacks may change so there is sufficient warning of the impending attack enabling the patient to drive his vehicle over to the curb or off the highway. In such an event the patient may resume driving a private vehicle.

There are very few laryngological conditions which interfere with the safe operation of a motor vehicle. However, individuals with seriously handicapping speech disorders or any irremedial deformities or diseases of the mouth, nose, and throat interfering with feeding, speech, or breathing should not operate a passenger transport or commercial vehicle. Patients with a tracheotomy should not drive a motor vehicle because of the possibility of sudden obstruction of the tracheotomy.

Surgery and Orthopedics

The role of acute surgical lesions as causes of traffic accidents is slight, for an individual so afflicted is unlikely to be driving. Chronic disabling surgical lesions, in those still able to drive, are apt to be compensated for and are not significant causes of traffic accidents. Of chief concern surgically are the severe injuries sustained by occupants of motor vehicles involved in accidents and how such severe injuries can be reduced through such means as car design, seat belts, and crash helmets. These problems are beyond the scope of this guide.

Many orthopedic handicaps may interfere with safe driving. A guide to aid physicians in evaluating such handicaps is available.[1] It is important to remember that the final acts of driving, however complicated the psychosomatic-mechanical reaction involved, are dependent on the biomechanical efficiency of the bones, joints, and muscles. Moreover, orthopedic aspects overlap other essential abilities for safe driving—for example, the effects of spinal immobility, in limiting the peripheral field of vision, which is so important, particularly at intersections.

The patient must be in such physical condition that he can control a motor vehicle with safety. This means he must have sufficient strength to control the vehicle; turn the steering wheel, and apply the brakes sufficiently to "slide the wheels." He must be able to reach all controls required in the operation of the vehicle, whether by mechanical means on the vehicle or by suitable prosthetic devices. Moreover, those so handicapped must demonstrate that they can successfully operate their vehicles in this manner.

Experience has shown that orthopedically handicapped persons do not as a rule meet with accidents more often than those not so afflicted. It is known that the handicapped person instinctively is more alert to danger and exercises more caution in driving. Ease of muscular fatigue in these individuals needs to be appreciated, but, again, most of these handicapped individuals are accustomed to regulating their energies and avoiding disabling fatigue.

Specific Requirements.—Specific requirements in persons are best considered from the standpoint of body regions as they relate to the static and dynamic demands upon the driver of a motor vehicle. Moreover, shifting of the line of gravity in the seated posture effects efficiency, comfort, and ability of driver performance, particularly in the orthopedically handicapped. All assessments with respect to driver performance must take cognizance of the variance in the center of gravity through the body of the driver and its effects upon the functional capacity of body parts.

Head and Neck Movements.—Relationships and mobility should be normal for operators of commercial and passenger transport vehicles. Variable degrees of restricted movements of the head and neck are compatible with safe operation of private vehicles.

Any limitation of rotation of the head by 50% or more by disease or splinting necessitates compensatory aids to enable these individuals to drive safely. Outside mirrors and swivel type bucket seats can sufficiently aid some of these people. In case of accident, especially when treatment is supplemented by any kind of supportive splinting or bracing, such individuals may be more vulnerable to injury and should be so advised by their physicians. Patients wearing a neck cast or brace should be advised not to drive until recovery has progressed to the point where pain and cervical restrictions of movement are minimal and external support is no longer necessary.

The patient with spastic torticollis should be advised not to drive a motor vehicle. Patients with mild congenital torticollis without pain or significant disability may be advised that it is safe for them to drive.

Thoracic Region of the Spine.—Patients with disabling diseases and deficiencies of the thoracic region of the spine should be advised against driving a commercial or passenger transport vehicle. Many compromises are possible with regard to private vehicles. Patients with arthritis and older injuries if associated with marked deformity or painful restrictions of motion or respiratory excursions should be advised not to drive a motor vehicle. However, proper bucket type swivel seating with restraining seat belt may provide sufficient compensation for some of these individuals. Patients with interscapular pain which causes restriction of motion of the shoulder joint and increases vulnerability to fatigue and irritability should be advised not to drive until they recover.

Mild to moderate degrees of scoliosis do not ordinarily interfere with safe driving. However, patients with severe grades of scoliosis, when it is accompanied by painful arthritis or ease of fatigue, should be advised not to drive a motor vehicle. The scoliotic patient may be helped by seating of the bucket type or other seating specially tailored to his needs, or possibly with the aid of a brace. However, those wearing braces should be carefully evaluated by the physician as to their ability to manipulate a motor vehicle safely. Individuals with extensions under the arms which could interfere with axillary circulation frequently are too incapacitated to drive safely.

Patients with osteoporosis are vulnerable to vertebral fractures from abrupt deceleration and should be so warned. Such patients can be safeguarded by bucket type seating and proper safety restraint, particularly shoulder harnesses and seat belts. With these aids they may be advised that it is safe to drive. Patients with myeloma of ribs and spine should be advised in a similar fashion.

Lumbar Region of the Spine.—The seated position imposes rather unusual stresses and strains on the lumbar region of the spine. These stresses may induce fatigue accompanied by irritability. The seated position calls for a certain amount of compensatory flattening of the normal lordotic curve, which is influenced to some extent by proper mobility in the hip joints. Stiffness of the hip joints puts added strain on the lumbosacral junction and additional flexion forces during abrupt forward decelerations thus making the lumbar vertebrae more vulnerable to compressive fractures. Patients with a stiff hip should be warned of this danger and encouraged to seek seating revisions and shoulder type harness and safety belt restraints for their own safety.

The lumbar region of the spine should be normal for drivers of passenger transport and commercial vehicles. Lumbar abnormality may not incapacitate an individual from safely operating a private vehicle.

Many patients with lumbar deformities, stiffness, and neuromuscular deficits from cord or nerve root defects are not fully competent to operate a motor vehicle under all conditions. Such patients should be advised appropriately to restrict their driving. Although arthritis, osteoporosis, congenital anomalies, and scoliosis commonly are disabling, power steering, power brakes, and semiautomatic transmission are helpful to most of these individuals, enabling them to drive a private vehicle with safety.

Patients with herniated lumbar disks with much pain should be advised against driving, particularly during acute attacks.

Upper Extremities.—Normal functions are required for drivers of passenger transport and commercial vehicles. A one-armed person, provided the one arm is a good one, can operate a private vehicle safely, especially one equipped with power steering and a wheel button. The same is true for the loss of one arm and one leg, which requires the balancing effects of proper protheses.

Hands on the wheel of an automobile, in addition to serving to balance the driver, also are helpful in bracing against rapid deceleration. Obviously, the grasping power of the hands is of basic importance. An adequate number of opposing digits to the thumb are essential for proper gripping. Each individual with impairment of hand function needs to demonstrate sufficient ability to operate properly his private motor vehicle. Power steering is of great assistance to many individuals so handicapped.

Lower Extremities.—Normal function is essential for drivers of passenger transport and commercial vehicles. However, with good arms, even absence of both legs may not prevent the safe driving of a private vehicle with proper protheses and perhaps special hand controls. During prolonged driving, fatigue will accrue from improper buttock and thigh support. Ankylosis of the hip, as it relates to low back disability, has been discussed already.

Deformities of the feet or legs which require special shoes or braces may also require special controls on the vehicle. The foot controls must be spaced far enough apart to avoid pressure on the accelerator when the brake is being sought.

Stability of Joints.—Stability of joints as well as mobility and strength should be evaluated in reaction to driving ability.

Neurological, Emotional, and Psychiatric Disorders

The unhospitalized patient with an emotional, neurological, or psychiatric disorder presents the conscientious physician with a difficult problem. The disability by its very nature may create a special hazard in the safe operation of a motor vehicle. Yet frequently there are strong socioeconomic justifications for the patient continuing to drive.

Inasmuch as several states have in recent years established special procedures for licensing individuals with certain neurologic and psychiatric disorders, physicians should secure copies of these laws and regulations from the state licensing authority and acquaint themselves with the procedures in order properly to advise their patients.

Neurological Disorders.—Convulsive disorders, including major or minor seizures, petit mal, or psychomotor epilepsy are the most frequently encountered neurological disorders impairing driving ability.

Epilepsy: Epileptic patients not receiving medicaments and who have been seizure free for a minimum of two years are considered good risks for the operation of private vehicles but should be advised not to drive a commercial or passenger transport vehicle. Such patients should be advised not to consume alcoholic beverages in any form for at least 24 hours prior to driving. Moreover, fatigue should be avoided and six hours should be the maximum number of hours behind the wheel in one day. Also, epileptic patients should be advised that night driving may be particularly dangerous because the photic stimuli from opposing headlights may precipitate a seizure. Emotional stress should be minimized by avoiding driving in peak traffic hours. These patients should be advised to secure a review of their progress and physical condition at least twice a year by a physician. Epileptic patients under medication should be advised not to drive a motor vehicle until they have been seizure free for a minimum of two years, and then they should drive only private motor vehicles. They should be advised to limit their driving to daytime and avoid rush hours. They represent a risk not only because of the likelihood of a seizure suddenly occurring while driving but, in addition, the medications may produce undesirable side-effects which interfere with driving capabilities.

Faintness, Syncope, and Episodic Weakness: It would be impossible to cover all the syndromes, diseases, or physiological disorders which produce these symptoms. It is important, therefore, that the pattern of these symptoms be evaluated carefully in terms of impairment of driving ability. The isolated occurrence probably is of little concern. Patients having a history of multiple occurrences should be advised not to drive a motor vehicle until a diagnosis can be established and satisfactory corrective measures have been instituted. In instances in which no diagnosis can be made and symptomatic therapy is not effective, the patient should be advised not to drive a motor vehicle.

Narcolepsy: Narcolepsy is rare and infrequently encountered. Its onset is usually during adolescence or adult years and its etiology is poorly understood. The treatment is symptomatic. Patients under treatment should be advised not to drive a motor vehicle until they have been symptom free for two years and are experiencing no adverse side-effects from medicaments. If it becomes desirable to discontinue treatment, such patients should be advised not to drive for two years. If there is no recurrence of symptoms, they may resume unlimited driving.

Disorders Affecting Muscular Control or Coordination: Paralysis agitans, poliomyelitis, hereditary chronic progressive chorea with mental deterioration (Huntington's chorea), multiple sclerosis, hereditary sclerosis, spinal form (Friedreich's ataxia), syringomyelia, muscular dystrophy, cerebral palsy, myasthenia gravis, tumors of the brain and spinal cord, cerebellar degenerative diseases, amyotrophic lateral sclerosis syndrome, post-traumatic syndromes, and intracranial suppurative processes affect muscular control and coordination. The foregoing list of diseases is not complete but suggests the wide variety of processes affecting the nervous system. Each of these will pose special problems with respect to the driving abilities of the individual patient.

The more serious disorders generally cause either rapid deterioration or sufficient functional disability of such degree that the patient will of his own volition cease driving. In those patients with more slowly progressing cases, when the disability reaches a point making driving unsafe, it is the physician's responsibility to recommend to the patient that he discontinue driving.

Mental Deficiency: Patients with an intelligence quotient below 70 and many borderline mentally defectives with an intelligence quotient between 70 and 80 are more susceptible to accidents than normal individuals when faced with emergency situations requiring accurate judgment or decisive action. Patients with intelligence quotients below 70 should be advised not to drive their private vehicles in rush hours, in congested traffic, or under other stress traffic conditions. These individuals also should be advised not to drive commercial or passenger transport vehicles.

Emotional Disturbances.—Many varied stresses and situations create in normal individuals a temporary emotional upset impairing their driving ability. The manifestations occur in three abnormal behavioral patterns. First, the individual is so absorbed in his problem that he is indifferent and inattentive to traffic and the world about him. Second, some individuals become greatly despondent, with actual depression and psychomotor retardation. Such individuals have sufficiently slowed reflexes to make driving a real hazard. Third, many such individuals become antagonistic, impulsive, or openly aggressive with loss of judgment and loss of sense of caution. Patients exhibiting any of these three types of symptoms should be advised not to drive a motor vehicle until they have recovered.

Some patients live under more or less permanent emotional stress. Until, with help and understanding, such patients have worked out an adequate adjustment to the situation, they should be advised not to drive a motor vehicle. Most patients under temporary or persistent emotional stresses producing either aggressive or depressive reactions are unaware of the increased likelihood of an accident. Such patients need to be made fully cognizant of the increased dangers inherent in their situation while being helped to work out a satisfactory solution.

As yet, only limited reliable data are available to aid in identifying drivers most likely to become involved in accidents. The characteristics most clearly related to repeated accidents or high accident rates are very low intelligence, youthfulness, and a personality make-up featured by egocentricity, aggressiveness, antisocial trends, and social irresponsibility.

Psychiatric Disturbances.—The psychoses, affective reactions, schizophrenic reactions, and paranoid reactions in the majority of patients present no recognizable morphologic changes, but the functional disability may be severe. In the majority of instances the frankly psychotic patient will be under hospital care and incapable of driving a motor vehicle. After hospitalization there are in many states special provisions for relicensing these individuals. Physicians should be familiar with these regulations. In exceptional instances where a frankly psychotic patient is being treated on an outpatient basis, the patient and a responsible member of the patient's family should be advised that the patient should not operate a motor vehicle.

Patients who have been returned to the community and require maintenance therapy with the ataractic drugs should be advised not to drive a motor vehicle if drowsiness or syncope occurs. Patients receiving maintenance therapy with the tranquilizers should be observed closely for possible deleterious side-effects from alcohol. Such effects have been reported with certain of the tranquilizer drugs.

Anxiety reactions, dissociation reactions, conversion reactions, phobic reactions, obsessive-compulsive reactions, and depressive reactions are among the conditions observed in the psychoneurotic patient. The patient with a psychoneurosis represents an unknown factor with respect to highway safety. Each case requires separate evaluation regarding alertness, social behavior, and possible psychomotor retardation. If no significant behavioral problem or drug therapy side-reaction exists, then the psychoneurotic patients may be advised that it is safe for them to drive. Careful appraisal, although often difficult, of the driving capacities of all these patients, with sound advice and recommendations to them, provides the physician with an exceptional opportunity for protecting both the safety of his patients and the public. In this manner physicians can make most significant contributions to the prevention of highway accidents.

Alcohol

Alcohol is the responsible factor in a large percentage of the motor vehicle accidents attributed to speed, reckless driving, and driving on the wrong side of the road. Detailed studies in selected areas show that approximately 50% of the fatal accidents involve a drinking driver. If this 50% figure holds nationally, then, in 1958, about 15,000 people died in accidents involving a drinking driver. Although valid data are not available, there is no doubt that many of the accidents which caused injury to about 5,000,000 people in 1958 involved a drinking driver. This situation urgently needs medical consideration.

Pharmacology.—Ethyl alcohol (i. e., grain alcohol, C_2H_5OH) is a central nervous system depressant, even though for years it was called a stimulant. Its effect on human beings is in all phases and stages a depressant. While many individuals will have a sense of exhilaration after consuming alcohol, this is not due to stimulation but to a depression of the inhibitory mechanism. The more recently acquired inhibitions are the first to be affected. Studies reveal that test subjects after consumption of alcohol almost unanimously believe that their performance is unimpaired or even better than usual, whereas objective testing demonstrates that performance is impaired. This, too, is evidence of a depressant action of alcohol—a depression of the critical sense. This depressant action of even small doses of alcohol is of obvious importance in the operation of motor vehicles.

Alcohol and Driving Ability.—Holcomb concluded from his studies that driving performance began to be impaired at a blood alcohol level of 0.05%, or 50 mg. per 100 ml. of blood. Lauer revealed that driving performance in many persons is impaired at an even lower level, 0.035%, and emphasized the importance, at this low level, of such factors as the impairment of judgment, observation, tolerance to glare, and sense of caution, even though muscular performance was not affected.

In 1950 the definitive study by Bjerver and Goldberg appeared and confirmed once again that "the role that alcohol plays in causing traffic accidents is probably considerably greater than appears from official statistics." They ascertained the average threshold of impairment of driving ability in expert drivers, accustomed to consuming moderate amounts of alcohol, as 0.035 to 0.040% alcohol in the blood.

Studies by Smith and Popham of the drivers involved in personal-injury motor vehicle accidents indicate that driving impairment begins at a blood alcohol level of 0.03%. Loomis and West reported in 1959 that "some impairment of ability to perform a simulated driving test could be detected in some individuals when the blood alcohol concentration was as low as 0.03%."

Alcohol Consumption and Blood Alcohol Level.—Almost everyone is interested in the practical aspect of how much liquor of one kind or another can be imbibed before reaching a blood alcohol level considered dangerous for driving. Numerous studies, using individuals accustomed to drinking, all are in full agreement that two 12-oz. bottles of 3.2% beer or 2 oz. of 100 proof whisky consumed within one hour will put the average moderate drinker in the zone of impaired driving ability, i. e., with over 0.035% alcohol in the blood. Three 12-oz. bottles of beer or 3 oz. of whisky will result in more that 0.05% alcohol in the blood of this same individual.

Rate of Oxidation and Elimination.—As the drinker is adding alcohol, the organism is oxidizing it in the liver and eliminating it through the kidneys and the lungs. The concentration of alcohol in the exhaled breath is proportional to the concentration of alcohol in the blood which is circulating through the lungs in a ratio of 2,100:1. The average person of 150 lb. (68 kg.) can oxidize and eliminate about one-third fluid ounce of alcohol per hour, decreasing the concentration of alcohol in his blood by approximately 0.015% per hour. Two hours will reduce the blood alcohol concentration about 0.03% if the individual does not consume more alcohol. This offers a clue to length of the necessary waiting period after drinking before driving.

Measurement of Blood Alcohol Levels.—While direct chemical measurement of the alcohol in the blood is probably the most accurate, the most convenient method is measuring the alcohol in the breath. Several excellent breath testing devices have come into being and are relied upon more and more since the breath alcohol quite accurately reflects the alcohol level of the blood circulating through the lung.

Physician's Advice on Drinking and Driving.—It is not important whether the blood alcohol level is determined on an ascending or descending curve of intoxication; also, the kind of alcoholic beverage consumed, the rapidity of its consumption, or whether it was consumed on a full or fasting stomach is not of material significance. Whether the individual is an experienced drinker with a high degree of tolerance or one who seldom drinks is not the important point. The only significant fact is the amount of alcohol in the individual's blood and the consequent impairment of his driving ability.

The average individual with a blood alcohol level of 0.05% or higher suffers significant deterioration of his driving skill and is a potential menace on the highway. What then, can practicing physicians do to prevent these thousands of deaths and injuries each year? First, patients must learn the basic facts of alcohol consumption and motor vehicle operation. One drink may be tolerated. Two drinks put one in the level of impairment for about two hours. Three drinks are too many.

Summary

The Committee on Medical Aspects of Automobile Injuries and Deaths has compiled in this guide a summary of the pertinent medical data presently available concerning the ability of an individual to operate a motor vehicle safely. Much research remains to be done on factors such as physical disabilities, certain physiological states, and drugs, in connection with safe driving ability. However, on the basis of present knowledge, it is believed that a conscientious medical evaluation of the individual's fitness to drive safely, with appropriate follow-up, can reduce motor vehicle accidents very significantly.

STATEMENT ON THE DOCTOR-DRAFT ACT

February 2, 1959

Honorable Carl Vinson, Chairman
Committee on Armed Services
U. S. House of Representatives
Washington 25, D. C.

Dear Chairman Vinson:

The purpose of this letter is to submit for the consideration of the Committee on Armed Services the position of the American Medical Association on H. R. 2260, 86th Congress, a bill, which, in part, would extend until July 1, 1963, the induction provisions of the Universal Military Training and Service Act.

With respect to the extension of the special provisions of this Act applicable to medical, dental, or allied specialists, the American Medical Association wishes to reaffirm its position which was outlined in testimony presented in May, 1957, before the House Armed Services Committee on the bill which subsequently was enacted as Public Law 85-62, approved June 27, 1957. At that time, the Association testified that "if the demands for the defense and security of our nation are such that, in the opinion of Congress, it is necessary to have a draft act to maintain the strength of our Armed Forces, then the extension of the present legislation would be one method to insure sufficient physicians for the military services."

The Association also recommended retention of the provisions of the law relating to the national, state, and local committees which advise the Selective Service System in regard to the selection of medical, dental, and allied specialists required by the services. These advisory committees consider, among other factors, the needs of the civilian population in the communities from which these physicians would be taken. The Association is pleased that this provision is a part of the current law.

In regard to specialist categories, the Association recommends, as it did previously in May, 1957, that the word "other" should be substituted for the word "allied" in this section of the law. This would authorize a selective call for other specialists, such as engineers, physicists, other scientists, etc., which might be needed by the military forces. Presently, the law provides only for the selective call-up of medical, dental, or "allied" specialists.

The Association believes that physicians should be registered and classified in the same manner as other citizens in the same age group, deferred for educational purposes in the same manner as other registrants, and called to active duty or inducted under the same general provisions as other registrants deferred for educational purposes.

It is noted that the pending bill proposes a four-year rather than a two-year extension of the Universal Military Training and Service Act. We believe this additional extension of time should be fully explained and justified to the Committee. We believe that this justification is necessary because scientific and technological advances have resulted in rapidly changing concepts of military manpower requirements. Consequently, there has resulted, directly or indirectly, current and projected reductions in the strength of the Armed Forces. It is conceivable that future manpower requirements may be subject to further downward revisions. A lesser period of extension of the law would permit a timely review of military manpower requirements in light of pertinent changes in the then current military situations. The Association believes that this would be particularly desirable with respect to the call-up of medical and allied specialists because of the increasing demands and requirements of the civilian population for the nation's medical and health resources.

As you know from our previous appearances before your Committee, the Association has had a keen and sustained interest in military medicine for many years. Through the Surgeons General of the military services, we have maintained a friendly and close working arrangement in the consideration and advancement of military medical affairs. We feel that the health of the nation requires a careful correlation of military and civilian medicine. In furtherance of this objective, the Association, working with the military services, has attempted to insure improvement in the utilization of medical manpower by the Armed Services and a strengthening of the career incentive program for medical officers.

On behalf of the American Medical Association, I would like to thank you for this opportunity to present our views on H. R. 2260 and to assure your Committee of our willingness to continue our assistance in providing the members of the military services with the finest medical care.

Yours sincerely,
F. J. L. Blasingame, M.D.

STATEMENT ON PROPRIETARY NURSING HOMES

January 26, 1959

Senator John J. Sparkman, Chairman
Subcommittee on Housing
Senate Banking and Currency Committee
Senate Office Building
Washington 25, D. C.

Dear Senator Sparkman:

I am writing this letter to you to express the official views of the American Medical Association with respect to Title II of S. 57, 86th Congress, which I understand, is now pending before your Committee. Our position with respect to this proposal, which would make proprietary nursing homes eligible for mortgage insurance, is one of active support.

Our deep interest in the subject of the health care of the aged and the occurrence of some significant recent developments have prompted me to mention certain activities in this field before outlining the specific reasons for our support of Title II of S. 57.

Since its beginning, more than a century ago, the American Medical Association has been deeply concerned with the medical aspects of caring for the aged. In recent years, however, our interest and activities in this connection have kept pace with the ever-increasing amount of national attention being given to the subject both within the government and among groups and associations outside government. This general trend is understandable, of course, since the proportion of our population over age 65 is increasing at an amazing rate. In 1900 there were only three million of these elderly citizens whereas now there are approximately fifteen million.

For the past several years the American Medical Association has had a Committee on Aging, composed of some of the leading medical authorities in the United States in this field, which has devoted its full effort to this problem. In addition there are forty-five Committees on Aging actively at work in the State medical societies. To facilitate and coordinate the work of these committees, a set of guides for their organization and operation has been developed and made available to them.

As a climax to a series of five regional meetings which were held last year, and in an effort to prepare a positive program for use by the state committees, an A. M. A. National Planning Conference for Medical Society Action in the Field of Aging was held in Chicago on Sept. 13-14, 1958. This Conference was attended by over 175 people including official state medical society representatives from 46 states and the District of Columbia, as well as 27 state health departments. A copy of the official proceedings of this Conference, together with a related brochure entitled "Health Aspects of Aging" are enclosed for the information of the Committee.

In our consideration of the health problems of the aged we have also given serious thought to effective methods of financing medical and hospital care. In considering this facet of the problem, it should be noted that enrollment of older people under voluntary health insurance has increased substantially in recent years. In the last several years alone the percentage of coverage has gone up approximately one hundred per cent. Presently, exclusive of the approximately three million older persons who receive public assistance, more than fifty per cent of those over age 65 have some form of health insurance. Nevertheless, in our opinion, there is a need for further expansion of voluntary health insurance coverage among the aged.

During the last year the Association has conducted or participated in numerous meetings and conferences with commercial insurance carriers and with state and national Blue Cross and Blue Shield Commissions to encourage still greater efforts in the development of new insurance programs and in the expansion of lower cost protection for persons over age 65. These companies, as well as Blue Cross and Blue Shield plans, are now engaged in intensive studies designed to develop new types of policies tailored to meet the needs of the aged ill; present retirement financing of health insurance policies with paid-up status at age 65; use of life insurance after 65 to pay for health care; and the application of deductible and co-insurance to permit coverage of costly illnesses at a low premium rate, among others.

In order to stimulate further the interest of state medical societies and individual physicians in this movement the House of Delegates of the Association approved the following resolution at its Clinical Meeting which was held in Minneapolis in December of 1958:

> For persons over 65 years of age with reduced incomes and very modest resources, it is necessary immediately to develop further the voluntary health insurance or prepayment plans in a way that would be acceptable both to the recipients and the medical profession. The medical profession must continue to assert its leadership and responsibility for assuring adequate medical care for this group of our citizens.
>
> Therefore, the Council on Medical Service recommends to the House of Delegates the adoption of the following proposal:
>
> That the American Medical Association, the constituent and component medical societies, as well as physicians everywhere, expedite the development of an effective voluntary health insurance or prepayment program for the group over 65 with modest resources or low family income; that physicians agree to accept a level of compensation for medical services rendered to this group, which will permit the development of such insurance and prepayment plans at a reduced premium rate.
>
> This recommendation has been studied and restudied by the Board of Trustees and has received its wholehearted endorsement.

In addition to the numerous and varied medical, scientific and socioeconomic activities being pursued in this field, physicians through their associations have, for some time, recognized the need for additional organizational weapons to attack these problems. For many years the American Medical Association was an active participant in the affairs of the Commission on Chronic Illness, in cooperation with representatives of the general public, industry, labor, agriculture, education, religion, social sciences, journalism, health, and welfare. One of a number of studies which were conducted was entitled "Nursing Homes, Their Patients and Their Care." A copy of this study which was published by the United States Public Health Service, is also attached for the information of your Committee.

Last year the American Medical Association joined with the American Hospital Association, the American Dental Association, and the American Nursing Home Association in the formation of The Joint Council to Improve the Health Care of the Aged. In broad outline the program of the Joint Council will include a coordinated plan of research designed to (*a*) determine the extent, utilization, and availability of facilities and the economic status and resources of the aged; (*b*) spearhead the expansion and experimentation in all types of voluntary health insurance coverage for the aged; (*c*) encourage the expansion of health care facilities for the aged; (*d*) encourage the development of community health services for the aged; (*e*) urge state and local legislative bodies to provide realistic financial support for medical, hospital, and nursing home care of aged public assistance recipients; and (*f*) appraise the problems of the aged who are mentally ill and provide an intensification of education, research, and action programs directed toward health problems of the aged at national, state and local levels.

In its work in connection with the over-all medical care problems of the aged, the American Medical Association has long recognized the importance of proper nursing home facilities. For this reason the Association has had a close relationship for some time with the American Nursing Home Association to work toward the development of higher standards for medical care in nursing homes. In February of 1958 the first National Conference on Nursing Homes and Homes for the Aged was held in Washington. Our Association was an active participant at that meeting. On Dec. 16, 1958, a Conference on Nursing Homes and Related Facilities between representatives of our Association, the American Hospital Association, the American Nursing Homes Association, Public Health Service, and Public Assistance Agencies was held in Chicago to discuss current activities and projected programs concerning facilities for the chronically ill and the aged. The purpose of this meeting was to seek a coordinated effort on the part of interested national organizations.

In addition the A. M. A. is currently making a survey of nursing homes throughout the United States. The American Nursing Home Association is also engaged in such a project and is surveying approximately five thousand member homes to obtain data on the cost of care to the patient, the type of patient in the homes and the type of medical care provided.

As an outgrowth of all of these various related activities in connection with the health care of the aged, our Council on Medical Service has prepared a *six-point program the details of which are outlined* in the attached brochure entitled "Medicine's Blueprint for the New Era of Aging."

In conclusion I should like to comment more specifically with respect to the provisions of Title II of S. 57, 86th Congress. As stated at the outset, the American Medical Association has approved and supports a government-insured loan program of the FHA type for non-governmental hospitals and nursing homes whether their ownership is of a nonprofit or proprietary character.

We have taken this position because we believe there is a critical need for new and improved facilities tailored to the specific health requirements of older citizens. It is our understanding that representatives of other organizations such as the American Nursing Home Association have or will appear before your Committee. They have evidence accumulated over recent years showing that they cannot provide service of the desired quality or quantity because they are unable to obtain the credit they need on reasonable terms to permit them to increase the number and size of adequate nursing home facilities.

Under the Hill-Burton program the federal government has for years been assisting public and nonprofit institutions through money grants. It is also our understanding that the Federal Housing Administration is presently offering mortgage insurance for construction of large nonprofit institutional-type homes for the aged which may have a section for those needing nursing care. In our opinion the immediate need is for a similar program of loan guarantees for proprietary organizations, since according to the latest statistics over seventy per cent of nursing home patients are cared for in such facilities.

In the administration of a grant program under the Hill-Burton system and a loan guarantee program under the Federal Housing Administration, we recognize the desirability of cooperation; however, we believe that the loan guarantee program proposed under Title II of the pending bill should be administered by the Federal Housing Administration without mandatory supervision or coordination with the Department of Health, Education, and Welfare.

I would like to request that this letter and attachments, to the extent possible, be made a part of the record of the hearings of your Committee. If you or any of the members of the Committee desire additional copies of the attached material or any further information from our Association, we shall be happy to provide you with anything we have.

Your willingness to permit the American Medical Association to present its views on the pending proposal is sincerely appreciated.

Very truly yours,
F. J. L. Blasingame, M.D.

HEALTH INSURANCE FOR PERSONS OVER 65 YEARS OF AGE

The action of the House of Delegates at its 1958 Clinical Session (Dec. 2-4) adopting a supplementary report of the Council on Medical Service urging the development of special medical care coverage at low premium rates for persons over age 65 brought an immediate response from Donald H. Stubbs, M.D., chairman of the board of directors of Blue Shield Medical Care Plans, the national association of Blue Shield plans.

Dr. Stubbs' announcement stated "Physicians everywhere have been urged to support this proposal and it is especially significant to the 120,000 doctors who are now participating in Blue Shield Plans, because they recognize their civic duty to help provide medical care to their patients under nonprofit programs with local control."

Dr. Stubbs said he believed local Blue Shield plans are ideally equipped to assist the medical profession in developing low cost coverage for senior citizens because each plan is operated under local medical society sponsorship in the area it serves and can put into effect any program to meet the exact specifications of coverage for elder citizens which physicians believe to be desirable. He also pointed out that the plans can be especially helpful in developing low cost coverage under their regular programs to some 2,500,000 subscribers over 65 years of age who have either been enrolled under Blue Shield group programs which ordinarily impose no age limits or who have joined Blue Shield before reaching 65 and have elected to continue their coverage on retirement.

The A. M. A. proposal, according to Dr. Stubbs, calls for a program under which physicians would accept a level of fees related to the modest resources and income of persons over 65 years of age. Such an arrangement, he indicated, would make it possible to provide the coverage at low rates and constitute a program that persons living on retirement incomes could easily afford.

Prepared by the Council on Medical Service.

According to the Blue Shield release, Dr. Stubbs indicated that each of the 64 Blue Shield plans in the United States will be asked to go to work immediately with local medical groups to draft benefit schedules and rates for coverage . . . to meet the needs of persons past 65 years of age. He added that guidance and information would be offered local plans by the national Blue Shield association in Chicago to expedite their efforts in developing their contracts.

To draft suggested patterns of coverages, special committees of the Blue Shield Board were created with the following twofold objectives: 1. To develop a practical pattern of benefits designed to meet the special medical needs of persons over 65 years of age. 2. To suggest a level of medical compensation for those benefits which would permit rates commensurate with the "modest resources or low family income" of persons in this age category.

Certain obvious facts were recognized in approaching these objectives. According to these committees, utilization and cost studies clearly indicated that the incidence of medical care for this age group is greater and, consequently, costlier. But these studies also produced evidence that the problem is not as severe as had been anticipated. It was the conclusion of the committees that the provision of adequate in-hospital medical care benefits must be a part of any program offered to this segment of our population.

Those studies reportedly revealed that, although the incidence of surgery increases in certain categories, other high cost and high incidence procedures, such as tonsillectomies, appendectomies, etc., common in the younger age group, can be minimized. It was the consensus that preexisting conditions will have to be covered after a reasonable (six months) waiting period.

After thorough consideration of these and other factors, the Blue Shield committees recommended that the following benefits be provided with reasonable premium rates to those over 65 years of age with "modest resources or low family income": (*a*) surgery; (*b*) anesthesia; (*c*) in-hospital medical care for 120 days; (*d*) diagnostic x-ray in the hospital, in the hospital outpatient department or doctor's office if hospitalization follows; and (*e*) radiation therapy.

During the course of preparation of the suggested programs, representatives of the Blue Shield staff conferred on two occasions with the Committee on Insurance and Prepayment Plans of the Council on Medical Service seeking its counsel and assistance.

On Jan. 26 the national Blue Shield office submitted the proposal to the local member plans. Subsequently, the Council on Medical Service directed the following memorandum to those constituent associations and component societies sponsoring or approving Blue Shield plans:

> As all of us know, there is a widespread interest in the problems of the so-called senior citizens. This includes problems concerned with health care, as well as the financing of such care. And, since voluntary health insurance is a primary means of financing health care, it is logical that the medical profession should look to insurance or prepayment programs to assist in meeting this new problem.
>
> Recognizing this, the House of Delegates, at its Minneopolis Session (December, 1958), adopted a report urging the development of special insurance and prepayment programs for persons over 65 with "modest resources and low family income." A copy of this report and the comments of the Reference Committee are enclosed for your information.
>
> As a step in implementing this report, the Committee on Insurance and Prepayment Plans of the Council on Medical Service conferred with representatives of Blue Shield to discuss the types of benefits that might be included in a program for those over 65. As a result, Blue Shield has set forth its suggestions for such coverage in the enclosed Policy Letter to its member plans. The Committee agreed in general with these proposals. It has, however, one important addition which it believes should also be considered. A major effort must be made to provide an alternative to hospitalization. It was agreed by the Committee that every effort should be made to provide for a specified number of office and home calls per year. Such a provision should also permit payment for calls to nursing homes as an alternative to hospitalization.
>
> With this addition, and in full recognition that income ceilings and physicians' fees for any program must be viewed in the light of local or state conditions, the Committee recommends that your medical society give earnest consideration to implementing programs set forth by Blue Shield and other groups, which would carry out the intent of the House of Delegates' action.
>
> It is the Committee's hope that the medical societies will initiate meetings to discuss this problem. The Committee would also appreciate being informed of any developments that may occur so that the House of Delegates, the Board of Trustees, and the Council on Medical Service may be aware of the progress being made.

The active interest of the private insurance companies is evident from the report of a special meeting of the Health Insurance Association of America held in New York City, Dec. 8, 1958. At that meeting a resolution was approved setting forth principles designed among other things to promote more rapid spread of hospital, medical, and surgical insurance among people aged 65 and over.

Principal features of the resolution are that insurers offering individual coverage (*a*) should continue and accelerate their progress in minimizing the refusal of renewal solely because of deterioration of health after issuance, (*b*) should promptly make available to insurable adults policies which are guaranteed renewable for life, (*c*) should encourage sale of permanent health care insurance where the need for this type of coverage exists, and (*d*) should promptly take steps if they are not presently doing so to offer insurance coverage to persons now over age 65. Insurers writing coverage on a group basis, the resolution added, should (*a*) aggressively promote soundly financed coverages that will continue after retirement and (*b*) encourage the inclusion in group contracts of the right to convert to an individual contract on termination of employment.

MEDICAL NEWS

ALABAMA

Change of Address.—The Medical Association of the State of Alabama announced that subsequent to Feb. 20 all mail for the association should be directed to the following address: The Medical Association of the State of Alabama, 19 S. Jackson St., Montgomery 4, Ala.

Personal.—Richard T. Eastwood, Ph.D., was appointed executive director of university affairs for the University of Alabama Medical Center, Birmingham, effective Oct. 15.——Dr. Durward L. Lovell was appointed director of medical education, Birmingham Baptist Hospitals, Birmingham. He will be responsible for directing the hospitals' intern training program.

ARKANSAS

Dr. Dinning Named Head of Biochemistry Department.—James S. Dinning, Ph.D., associate professor of biochemistry, University of Arkansas Medical Center, Little Rock, was promoted to professor and head of the department of biochemistry to succeed Paul L. Day, Ph.D. Dr. Day resigned recently to become the first scientific director of the United States Food and Drug Administration. Dr. Dinning joined the university faculty in September, 1948, as an assistant professor and left in 1952 to spend one year at the University of Pittsburgh. He is a special consultant to the United States Public Health Service's Metabolism and Nutrition Study Section and this year closed out a five-year term as associate editor of *Nutrition Review*. He is on the editorial board of the *Journal of Nutrition* and is secretary of the Southwest Section of the Society for Experimental Biology and Medicine.

CALIFORNIA

Center for Cardiovascular-Renal Diseases.—A center for intensive treatment of cardiovascular-renal diseases and electrolyte problems was established and is in operation at Saint Joseph Hospital, Burbank. The center is in readiness to receive patients with cardiac or renal failure who may benefit from use of an artificial kidney, "medical" heart-lung machine, or with use of modern physiological monitoring equipment. The center is headed by Dr. Peter F. Salisbury.

University News.—Dr. G. Meyer-Schwickerath, of the University of Bonn, spoke Nov. 14 at the Stanford University School of Medicine on "Treatment of Retinal Lesions and Intra-Ocular Tumors with the Light Coagulator." Dr. Meyer-Schwickerath's lecture was part of a four-day postgraduate conference on ophthalmology at the Medical School devoted to "The Causes of Failure in Intra-Ocular Surgery and Related Problems."

CONNECTICUT

Physiologist Wins International Award.—Dr. John F. Fulton, physiologist at the Yale School of Medicine, New Haven, was named 1958 recipient of the annual George Sarton medal of the History of Science Society, given annually for "outstanding contributions in history of science." Dr. Fulton is a former chairman of the department of physiology at Yale and now holds the rank of Sterling Professor of the History of Medicine. The George Sarton medal was created in honor of Dr. Sarton, Belgian scholar and professor of the history of science at Harvard, who died in 1956. Dr. Sarton founded the History of Science Society in 1912 and its publication, *Isis*, in 1912. The medal was created in 1955 and made possible by the Charles Pfizer Company. Dr. Sarton himself was the first recipient.

Personal.—Dr. David Seligson, formerly associate professor of clinical chemistry in medicine, University of Pennsylvania School of Medicine, Philadelphia, was appointed director of laboratories at Grace-New Haven Community Hospital and associate professor of medicine in the Yale University School of Medicine, New Haven.——The appointment of Dr. Morris A. Wessel, New Haven, to represent the Connecticut State Medical Society on the Governor's Committee on Children and Youth was announced. Dr. Harold M. Clarke, New Britain, was appointed to represent the society at a national conference on the medical care of veterans and their dependents.

FLORIDA

Society News.—The Board of Governors of the Florida Medical Association has announced the appointment of Mr. William Harold Parham as executive director.——The Greater Miami Eye, Ear, Nose and Throat Society, which meets quarterly in March, May, October, and December on Thursday evenings at the McAllister Hotel, Miami, has elected

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

the following officers for 1959: president, Dr. Mariano B. Caballero; vice-president, Dr. Joseph Freeman; secretary-treasurer, Dr. H. Carlton Howard.

HAWAII

Society News.—The following have been elected officers of The Honolulu Pediatric Society for 1959: president, Dr. Duke Cho Choy, Honolulu; recording secretary, Dr. Frances F. Nakamura, 1481 S. King St., Honolulu, Hawaii; corresponding secretary-treasurer, Dr. Calvin C. J. Sia, 1305 Kalakaua Ave., Honolulu, Hawaii.

IDAHO

Society News.—The newly elected officers of the Idaho Academy of General Practice are: president, Dr. Joseph G. Wilson, Moscow; president-elect, Dr. Arch T. Wigle, Pocatello; secretary-treasurer, Dr. Walter W. Wilson, Coeur d' Alene; A. A. G. P. delegates, Drs. Asael Tall, Rigby, and Ralph Buttermore, Grangeville; alternates, Drs. Aldon Tall, Rigby, and Louis F. Lesser, Boise.

ILLINOIS

Clinic for Juvenile Research at Jacksonville.—The State Department of Public Welfare announced Jan. 29 that its tax-supported Institute for Juvenile Research is opening a new regional medical clinic at the Infirmary in the Illinois School for Deaf to provide psychiatric, psychological and psychiatric social services to the emotionally disturbed child and his family for children under 18 years of age residing in Adams, Brown, Cass, Morgan, Pike, Schuyler, and Scott counties. Application forms may be secured from the Springfield regional office or local health departments. Address inquiries to the Institute for Juvenile Research, 404 State Office Bldg., Springfield.

Chicago

Dr. Sulzberger to Give Pusey Lecture.—The William Allen Pusey Lecture of the Chicago Dermatological Society will be given March 18, 7 p. m., at the Illini Union, 715 S. Wood St. Dr. Marion B. Sulzberger, chairman, department of dermatology and syphilology, New York Skin and Cancer Hospital and New York University Postgraduate Medical School and Hospital, will speak on "Some New Aspects on the Biology of the Skin." Preceding the lecture there will be dinner at the Illini Union at 6 p. m. (reservations $4.75 per plate). This is an open meeting and all physicians are invited to the dinner and lecture.

University News.—Dr. J. F. Tait, of the Medical Research Council of Middlesex Hospital Medical School, London, and The Worcester Foundation for Experimental Biology, Shrewsbury, Mass., spoke on "The Secretion and Metabolism of Aldosterone in Normal and Pregnant Subjects" at The Chicago Medical School, Dec. 3.

Name Chairman of Surgery Department.—Dr. John L. Keeley was named professor and chairman of the department of surgery at Loyola University Stritch School of Medicine and head of surgery at Mercy Hospital, succeeding Dr. Harry A. Oberhelman, who will continue on the Mercy hospital staff as a member of the Loyola medical faculty. Dr. Keeley was one of the two American specialists called to Rome in 1958 to attend the late Samuel Cardinal Stritch, archbishop of Chicago. While in Rome he was named a Knight of Gregory of his late Holiness, Pope Pius XII, and Cardinal Stritch conferred the honor upon him. Dr. Keeley was an Arthur Tracy Cabot Fellow in surgery at Harvard in 1936 and 1937, and stayed at Harvard as the *Harvey Cushing Fellow in surgery the following* year. Dr. Oberhelman was chief of surgery at Loyola medical school and Mercy hospital for 17 years.

Hospital Plans Research Expansion.—Ten Chicago business leaders are launching a new board of governors of the Research Institute of Michael Reese Hospital & Medical Center, Mr. Irving B. Harris, president of the center, has announced. Purpose of the new board will be to "plan, program, and finance expansion of medical research." For the first time, Michael Reese reportedly will top one million dollars in research expenditures. About two-thirds of the funds for medical research at Michael Reese comes from governmental agencies, foundations, and such health organizations as the American Heart Association, the American Cancer Society, the American Fund for Psychiatry, the National Nephrosis Foundation, and the Damon Runyon Fund. Michael Reese's Medical Research Institute was founded in 1929, and now numbers 11 full-time departments and three affiliated laboratories.

KANSAS

Regional Physicians Meeting in Wichita.—The American College of Physicians, Kansas Region, will meet March 20 at the Allis Hotel, Wichita. Dr. Fred J. McEwen, of Wichita, is governor of the College for Kansas. Papers which include invited authors are:

Experiences with Cineangiography, Drs. Marvin I. Dunn, Thurl E. Andrews, and E. Grey Dimon, Kansas City.
Clinical Diagnosis of Ventricular Septal Defect, Dr. Alberto Benchimol, Kansas City.
Chronic Nonspecific Pericarditis with Effusion; Case Report, Drs. David Lukens, Calvin R. Openshaw, and Robert C. Tout, Hutchinson.

Milk Alkali Syndrome, Dr. Joseph Meek, Kansas City.
Liver Pathology Following Isoniazid (Marsilid) Toxicity, Dr. Charles G. Hermann, Topeka.

The sessions will close with a dinner (6:15) at which Dr. William C. Menninger, regent of the college, will be guest speaker, presenting "Brains Before Bricks." For information write the American College of Physicians, 4200 Pine St., Philadelphia 4.

MASSACHUSETTS

Appoint Acting Department Heads.—The appointments of Eric G. Ball, Ph.D., as acting head of the department of biological chemistry and of Dr. Maurice M. Tolman as acting head of the department of dermatology were announced by Dr. George P. Berry, dean of the faculty of medicine, Harvard University, Boston. Dr. Ball, who has served as a member of the faculty of medicine at Harvard since 1940, succeeds Dr. A. Baird Hastings, who has retired and has become a member of the resident research staff at the Scripps Clinic and Research Foundation, La Jolla, Calif. Dr. Ball is professor of biological chemistry at Harvard and chairman of the division of Medical Sciences. Dr. Tolman, assistant clinical professor of dermatology at Harvard, where he has taught since 1940, succeeds Dr. Chester N. Frazier, who retired in 1958. Dr. Tolman is acting chief of the dermatology service at the Massachusetts General Hospital.

MICHIGAN

Personal.—Dr. Starling D. Steiner has been appointed medical director of General Motors, effective December 1. He succeeds Dr. Max R. Burnell, who retired on Nov. 1. Dr. Steiner, who has been medical director of the Oldsmobile Division of General Motors in Lansing since 1946, is currently serving as treasurer of the Ingham County Medical Society.——Dr. William A. Fellner has been appointed medical director of General Motors central office, Detroit, effective Feb. 1. He replaces Dr. William J. Fulton, who is retiring.

Annual Conference on Nutrition.—The fifth annual Nutrition Conference, sponsored by Wayne State University College of Medicine, will be held on Friday, March 20. Speakers on the general subject "Inorganic Factors in Nutrition" will include George K. Davis, Ph.D., of the University of Florida; Dr. William B. Schwartz, of Tufts Medical School; Dr. Carl V. Moore, of Washington University; and David M. Hegsted, Ph.D., of Harvard University. Members of the American Medical Association are cordially invited. For information write Mr. James M. Orten, Chairman, Publicity Committee, Wayne State University, 1401 Rivard St., Detroit 7.

Society News.—The Michigan Academy of General Practice congress of delegates convened Nov. 11 and the following officers were elected: Dr. Clark W. Royer, Battle Creek, installed as president by Dr. Francis P. Rhoades, Detroit, retiring president; Dr. Howard C. Rees, Grosse Pointe, president-elect; Dr. Earl C. Long, Detroit, secretary; Dr. Lyle W. Korum, Detroit, treasurer; Dr. C. Howard Ross, Ann Arbor, speaker; Dr. Aaron C. Stander, Saginaw, vice-speaker.

MISSISSIPPI

Society News.—The Mississippi Academy of General Practice concluded its 10th annual meeting recently with Dr. A. T. Tatum, Petal, raised to presidency. Newly elected officers are Drs. R. J. Moorehead, Yazoo City, president-elect; Louis F. Rittelmeyer, Jackson, vice-president; and J. R Bane, Jackson, secretary-treasurer.

MISSOURI

Dr. Mason to Give Annual Lecture.—Dr. Michael L. Mason, professor of surgery, Northwestern University School of Medicine, will present the 10th annual Dr. F. G. Thompson Sr. Lecture on Thursday evening, May 21, at the Thompson, Brumm, Knepper Clinic and Hospital, in St. Joseph. The title of the lecture will be "Treatment of Acute Injuries to the Hand."

NEW JERSEY

Annual Heart Seminar.—The New Jersey Heart Association will hold its annual scientific seminar in the Essex House Hotel, 1050 Broad St., Newark, April 1, at 2 p. m. The program is as follows:

Surgical Approach to Coronary Artery Disease, Dr. Claude S. Beck, Cleveland.
Current Views on the Causation of Atherosclerosis, Dr. Russell L. Holman, New Orleans.
Controversial Views in the Management of the Atherosclerotic Patient, Dr. Samuel A. Levine, Boston.
The Recognition of the Atypical Coronary Occlusion, Dr. William Likoff, Philadelphia.

Dr. Norman Reitman is president of the New Jersey Heart Association, and Mr. Howard W. Dayton, 60 Park Place, Newark 2, N. J., is executive director.

NEW YORK

Welsh Guest.—Dr. Arthur G. Watkins, Dean of Clinical and Postgraduate Studies at the Welsh National School of Medicine, Cardiff, England, was the guest of the pediatrics department at Albany Medical College Feb. 16 and 17. Dr. Watkins, who is also professor of child health at the Welsh School and pediatrician at the United Cardiff Hospitals, served as professor pro tem of pediatrics during his stay. He addressed junior medical students on Monday, and spoke before the entire student body and faculty on Tuesday.

Open Applications for Medical Supervisor.—The New York State Department of Civil Service will accept applications until April 10 from qualified candidates for the position of supervisor of school medical services, State Education Department. No written or oral test will be required. Candidates will be rated on their training and experience in relation to the duties and requirements of the position. At present there is one vacancy in Albany and another is anticipated. Candidates must possess a license issued by New York State to practice medicine or be eligible to enter the examination for such a license and must have two years of satisfactory experience in the practice of medicine, of which one year must have included service as a school physician. The annual salary range for this position, which is open only to legal residents of New York State, is $8,750 to $10,520. A supervisor of school medical services performs field and office work in the supervision and guidance of the health services program in the schools of the state. For applications write to Recruitment Unit, New York State Department of Civil Service, State Campus, Albany 1, N. Y.

•

New York City

Dr. Brunsting to Give Memorial Lecture.—The department of dermatology and syphilology of New York University Post-Graduate Medical School announced that the second Howard Fox Memorial Lecture will be given by Dr. Louis A. Brunsting Sr., April 21, 8 p. m., in the auditorium of Alumni Hall, 550 First Ave., New York City. The title of his talk will be "Porphyria Cutanea Tarda."

Dr. Wangensteen to Lecture.—The annual Walter L. Niles Memorial Lecture, sponsored by Nu Sigma Nu, Tau Chapter, will be given by Dr. Owen H. Wangensteen, chief of surgery, University of Minnesota, Minneapolis, at 8 p. m., March 18, in the auditorium of the Cornell University Medical College, 1300 York Ave., on "Studies in Peptic Ulcer." A dinner in honor of Dr. Wangensteen will be held before the lecture. The lecture is open to medical students and members of the profession.

Hospital News.—The celebration of the 100th anniversary of the third (NYU) surgical division of Bellevue Hospital Center was a highlight of the New York University College of Medicine Alumni Day ceremonies Feb. 21. Dr. Frank B. Berry, assistant secretary of defense (health and medical) and former director of Bellevue's first surgical division, received the University Bronze Medal and gave the principal address of the day. Additional awards presented were the association's annual distinguished service award to Dr. John H. Mulholland, chairman, department of surgery, and the presidential citation to Dr. Henry M. Scheer, former president of the association.

Memorial Fellowship for Cancer Research.—The New York Cancer Research Institute awarded the first Oliver E. Spencer Memorial Fellowship to New York University College of Medicine. The fellowship, established by friends and relatives of the late Oliver E. Spencer, who died of cancer at the age of 25, will provide a one-year training and research scholarship to a physician specializing in cancer and selected by Dr. Donal Sheehan, dean. The first incumbent is Dr. Erlinda Tobillo Novales, of Manila, The Philippines. Upon receiving her M.D. degree in 1955 from Santa Tomas University, she came to the United States for her residency training at New York City's Gouverneur Hospital and the New York Infirmary, where she is now chief resident in medicine.

Neurological Institute Celebrates Anniversary.—The year 1959 marks the 50th anniversary of the founding of The Neurological Institute of New York, specifically set up as a specialty hospital for the medical and surgical treatment of the nervous system. The institute in 1929 became affiliated with the Presbyterian Hospital of New York as a part of the Columbia-Presbyterian Medical Center. To commemorate the institute's 50th anniversary, a series of special events have been planned by Columbia University and the Presbyterian Hospital, and by various societies in neurology and neurosurgery. On March 10 a joint meeting of the New York Neurological Society and the Section of Neurology and Psychiatry of the Academy of Medicine was held. On April 27-28 the Society of Neurological Surgeons will hold its 50th meeting at the institute. A special anniversary celebration will be held at the Columbia-Presbyterian Medical Center May 15-16. Scientific sessions at which alumni and guests will speak will be held and there will be a commemorative dinner at the Waldorf-Astoria Hotel.

On May 16 a special convocation of Columbia University and the Presbyterian Hospital will be held at the Medical Center.

PENNSYLVANIA

Philadelphia

Personal.—Dr. I. S. Ravdin, vice-president for medical development, University of Pennsylvania, and Dr. John McK. Mitchell, vice-provost of the university and dean of the School of Medicine, were appointed to the Surgeon General's Consultant Group on Medical Education, Dr. Leroy Burney, surgeon general of the U. S. Public Health Service has announced.——Dr. Orville C. King was named director of the division of surgery for Pennsylvania Hospital department for sick and injured, Eighth and Spruce Streets. This announcement coincides with Dr. King's appointment as professor of clinical surgery, University of Pennsylvania School of Medicine.

RHODE ISLAND

Dr. Dailey Appointed State Health Director.—Governor Christopher Del Sesto of Rhode Island announced the appointment of Dr. Jeremiah A. Dailey, of Edgewood, as director, Department of Health, State of Rhode Island. Dr. Dailey retired from the United States Army at Fort George G. Meade, Md., Jan. 31. At the time of his retirement he was commanding officer, 68th Medical Group.

Hospital News.—Dr. Henry N. Harkins, professor of surgery and executive officer, department of surgery, University of Washington School of Medicine, Seattle, and surgeon-in-chief, King County Hospital (Seattle), will serve as surgeon-in-chief pro tempore at the Rhode Island Hospital, Providence, on March 19-21.

TENNESSEE

University News.—Dr. James S. Speed, head of the department of orthopedic surgery, University of Tennessee College of Medicine, Memphis, since 1941, has resigned his administrative duties but will continue as professor in the department. Dr. Speed's position as head of the department will be taken by Dr. Harold B. Boyd, who was advanced from associate professor to professor.

TEXAS

Dr. Wallace Wins Caldwell Award.—Dr. Stuart A. Wallace, chairman, department of pathology, was presented with the George T. Caldwell award, naming him "Pathologist of the Year for the State of Texas" at a meeting of the State Clinical Pathologists in Houston. The presentation was made at a banquet Jan. 24 "in recognition of long and distinguished service to mankind in the field of Pathology in Texas." Dr. Wallace has been associated with Baylor College since it was located in Dallas and became chairman of the department when the Houston move was made. The award, in memory of the late Dr. George T. Caldwell, who was professor of pathology at Baylor College of Medicine in Dallas, was established by Mrs. Caldwell and family about five years ago.

VIRGINIA

Meeting of Physicians in Hot Springs.—The American College of Physicians, Virginia Region, will meet March 21 at the Homestead, Hot Springs. Thirteen papers are scheduled for presentation, including the following which have invited guest authors:

Evaluation and Management of Electrolyte Problems in Heart Failure, Drs. Julian R. Beckwith Sr., Nuzhet O. Atuk, and J. Edwin Wood Jr., Charlottesville.

Pathogenesis of the Anemia in Myxedema, Drs. Jason E. McClellan and Byrd S. Leavell, Charlottesville.

Long-Term Anticoagulant Therapy, Drs. Frank E. Taylor, Charles L. Crockett Jr., and R. Earle Glendy, Roanoke.

The Coagulation Deficiencies with Report of a Case of Christmas Disease, Dr. Harry I. Johnson, Roanoke.

The Co-Existence of Pheochromocytoma and Unilateral Adrenocortical Hyperplasia, Drs. Gerald A. Williams, Charlottesville, William W. S. Butler, III, Roanoke, and Kenneth R. Crispell, New York City.

Clinical Usefulness of a Potent New Oral Diuretic, Drs. Gordon F. Cavell, Eugene M. Wyso, and David W. Richardson, Richmond.

Cardiotoxic Effects of Quinidine and Its Treatment with Molar Sodium Lactate, Dr. Dewey J. Bailey, Charlottesville.

A business meeting will precede a meeting with the Virginia Society of Internal Medicine at 4 p. m. Guest speaker will be Dr. Dwight L. Wilbur, San Francisco, president of the college. Dr. Charles M. Caravati is governor of the college for Virginia.

WEST VIRGINIA

Surgeons Meeting in White Sulphur Springs.—The annual meeting of the West Virginia Chapter of the American College of Surgeons will be held at The Greenbrier in White Sulphur Springs, April 3-4. Dr. Cornelius E. Sedgwick, of the Lahey Clinic, will present papers on "Portal Hypertension," "Tumor of the Neck," and "Surgical Treatment of

Thyroid Disease." Dr. David M. Hume, chairman, department of surgery, Medical College of Virginia, Richmond, will speak on a surgical subject of general interest. A cordial invitation has been extended by the West Virginia Chapter to all practicing physicians in the state. Information may be obtained by writing Dr. Victor S. Skaff, Secretary, West Virginia Chapter, ACS, 807 Atlas Building, Charleston 1, W. Va.

Appoint Acting Director of Mental Health.—Dr. Margaret T. Ross, director of community service, West Virginia State Department of Mental Health, was named by Governor Cecil H. Underwood as acting state director of mental health. She succeeds Dr. William B. Rossman of Charleston, who resigned. Dr. Richard J. Lilly, of Weston, superintendent of Weston State Hospital, had been appointed as successor to Dr. Rossman, and he came to Charleston and took the oath of office. However, late in January the question of Dr. Lilly's eligibility for the office was raised, inasmuch as he has not been a citizen of West Virginia for one year, as required by state law. On Feb. 4, the appointment of Dr. Lilly was withdrawn temporarily by Governor Underwood, who at that time indicated that he will reappoint him to the office next May, when he will have been a resident of the state for a year.

WISCONSIN

Dr. Morton Wins Award.—Newton E. Morton, Ph.D., assistant professor of medical genetics in the University of Wisconsin Medical School, Madison, was named to receive the Lederle Medical Faculty award of $18,000, given by the Lederle Laboratories and designed "to provide support for continued development of a promising teacher and investigator in fields of medicine and human biology." Dr. Morton, who serves as an associate editor of the *American Journal of Human Genetics*, will be supported under the grant for three years.

GENERAL

Booklet on Manuscript Preparation.—To facilitate the work of authors and editors of their journals, S. Karger, Inc., recently issued a booklet containing some rules for the preparation of manuscripts and bibliographies with a list of abbreviations of titles of current medical periodicals. The abbreviations of titles of periodicals have been taken with some minor deviations, from the list of World Medical Periodicals compiled by the World Medical Association based on the World List of Scientific Periodicals prepared under the auspices of UNESCO. The booklet has also been issued in German and French. For information write S. Karger, Inc., Swiss Bank Corporation, New York City.

Citizens' Committee on Health.—*Formation of an* ad hoc citizens' committee to increase public understanding of the principles underlying increased United States support of international health work was announced Feb. 12 by Dr. Howard A. Rusk in an address before a Brotherhood Week Luncheon of the National Conference of Christians and Jews in New York City. General Omar Bradley is chairman of the new group, known as the Committee on Health for Peace, and Detlev W. Bronk, LL.D., president, Rockefeller Institute for Medical Research, is chairman of its Scientific Advisory Committee. The Committee on Health for Peace will not engage in fund-raising activities; nor will it attempt to duplicate the work of the National Citizens Committee for the World Health Organization. Its function will be solely to increase public understanding of the importance of international cooperation in health and medical research. The activities would be entirely educational and would be initially centered on the International Health and Medical Research Act of 1959 which has been introduced in the Senate by Senator Lister Hill, Alabama, with 58 senators as co-sponsors, and in the House of Representatives by Representative John Fogarty, Rhode Island.

Invite Nominations for Research Award.—Nominations for the eighth Kimble Methodology Research Award are being accepted until June 1, 1959. This award, which gives recognition to the application of scientific knowledge to the Public Health Laboratory, was established by the Kimble Glass Company of Toledo, Ohio (subsidiary of the Owens-Illinois Glass Company), and is sponsored by the Conference of State and Provincial Public Health Laboratory Directors. The award of $1,000 and silver plaque will be presented at the annual meeting of the conference to be held in Atlantic City, N. J., in October. Rules governing nominations include:

(1) The candidate's work should be *either:*
  a. A fundamental contribution which serves as a baseline for development of diagnostic methods which fall within the province of the public health laboratory.
  b. The adaptation of a fundamental contribution to make it of use in a diagnostic laboratory.
(2) Candidates should be from the United States, its territories, or Canada.
(3) Nominations must be covered by six reprints with six summaries and bibliography or, if reprints are not avail-

able, by six summaries with bibliography. A statement which justifies the recommendations of the study must be included.

(4) Nominations may be made by the authors, associates, or by others. Documentary evidence, etc., should not be signed by the nominator. The nomination, however, should be accompanied by a letter of transmittal.

(5) Nominations received after June 1 will be considered for nomination in 1960.

(6) Nominations of a piece of work where there is more than one author is permissible. (If such work is selected, division of the cash award shall be arranged between the workers themselves.)

(7) The materials submitted to the Nominating Committee will not be returned to the sender.

Send nominations to E. T. Bynoe, Ph.D., Chairman, Nominating Committee, Kimble Award, Laboratory of Hygiene, Department of National Health and Welfare, Ottawa, Ontario, Canada.

CANADA

Prize for Paper on Fertility.—The Canadian Society for the Study of Fertility announced the award of the 1958 "Ortho" prize to Dr. Charles P. Leblond and Assistant Professor Y. Clermont, of the department of anatomy, McGill University, for their paper on "Differentiation and Renewal of Spermatagonia in the Monkey Macacus Rhesus." The "Ortho" prize was $1,000 for 1958, as the prize of $500 for 1957 was not awarded and had accumulated. Those interested in submitting a paper to the society for the 1959 "Ortho" prize of $500 must do so before June 1. Details may be obtained through Dr. Jean F. Campbell, Secretary-Treasurer, The Canadian Society for the Study of Fertility, 238 Queen's Ave., London, Ontario.

FOREIGN

Pediatric Convention in Italy.—Under the auspices of the Italian Society for Pediatrics (Societa Italiana di Pediatria) an International Pediatric Convention of the Latin Nations, will be held in San Remo, Italy, Sept. 24-27. The convention will be under the chairmanship of Prof. Giovanni De Toni, director of the pediatric clinic "Gaslini" of the University of Genova. The topics for discussion will be the following:

(1) Regional Pathology—the speakers chosen will report on the infantile pathology predominant in their respective regions, and on its changes during the last 20 years.

(2) Disease of Metabolism—the speakers will report on the specific topic of research.

(3) The Growth of the Child, Normal and Pathological Conditions.

Papers on the three topics will be accepted. For any information write to the Secretaries of the Convention (Dott. Prof. Ettore De Toni e Dott. Prof. Piero Salomone) c/o Pediatric Clinic "Gaslini," Genova-Quarto, or to the President of the Executive Committee: Dott. Prof. Giuseppe Cotellessa c/o Azienda Autonoma di Soggiorno e Turismo, Palazzo Riviera, San Remo (Italy).

Congress of Red Cross in Spain.—Dr. Carlos Blanco Soler, president of the first National Medical Congress of the Red Cross of Spain, has announced that the congress will be held in Madrid, May 20-23, under the auspices of the Higher Assembly of the Red Cross. Official topics are as follows:

Radioactivity.
Congenital Heart Diseases: Clinical, Diagnosis and Treatment of Interauricular Defects.
Rehabilitation and Recuperation of Invalids.
Blood Transfusion.

There will be a symposium on medicine and surgery of emergency, with Dr. Soler presiding. For information and registration write the Secretaria General Asamble Suprema, Paseo de Eduardo Dato, 16, Madrid, Spain.

Congress of Health Workers in Paris.—The sixth International Health Workers' Congress and Equipment Exhibition will be held in Paris, at the Parc des Expositions (Porte de Versailles), June 9-12 under the auspices of the journal "Techniques Hospitalieres Medico-Sociales et Sanitaires." It will be organized under the patronage of the French Minister of Public Health and the Population. The central theme will be "The Patient in the Hospital of the Future—The Functions of the Health Team." The chairman of the congress is Dr. Le Gorgeu, member of the Council of State and chairman of the National Committee for Hospital Organization. Hospital workers from all countries are cordially invited to participate. A hospital exhibition will include models of operating suites, wards, laboratories and technical equipment. Information on the program, exhibition space, hotel accommodation, etc., may be obtained from the Secretary-General, 37 rue de Montholon, Paris 9e.

DEATHS IN OTHER COUNTRIES

Dr. Gerin–Lajoie Dies.—The president-elect of the World Medical Association, Dr. Leon Gerin–Lajoie, Canadian gynecologist, died Feb. 14. He was president of the International Federation of Obstetricians and Gynecologists and vice-dean of the faculty of medicine at the University of Montreal. Dr.

Gerin-Lajoie was a founder of the Quebec division of the Canadian Medical Association and had served as its president.

CORRECTION

Report on 1958 Mortality.—In an item appearing in the Feb. 14 issue of The Journal, Medical News section, under this side head, the figures 916 per 1,000 and 912 should have read 9.6 and 9.2, respectively.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. Applications now on file. *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application was Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application was Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *I. Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates. Candidates who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Deadline for receipt of new and reopened application for the 1960 examinations is Aug. 1, 1959. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part I.* Washington, D. C., Denver, Colorado and Rochester, Minn., Mar. 26-27. Deadline for filing application was Nov. 30. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Boston, April 16-19. Final date for filing application was Feb. 28. Sec., Dr. Edward B. Smith, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Public Health.* Minneapolis, Boston, Baltimore, Chapel Hill, North Carolina and New Orleans, April 9-11; Berkeley, Calif., April 23-25; Pittsburgh, April 16-18. *Occupational Medicine.* Chicago, April 24-26. *Aviation Medicine.* Los Angeles, April 24-26. Final date for filing all applications is March 16. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New Orleans, Mar. 16-17; Chicago, Oct. 19-20; New York, Dec. 14-15. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application was Nov. 1. *Examination.* Chicago, June 2-4. If needed a special examination will be offered at this time in Nuclear Medicine to diplomates in Radiology or Therapeutic Radiology. The deadline for filing applications is April 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* Los Angeles, September. Final date for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

GOVERNMENT SERVICES

NAVY

Tissue Bank Training Course.—A two-week Tissue Bank Training Course offered at the National Naval Medical Center, Bethesda, Md. is now available to any eligible inactive naval reserve medical officer. This training may commence on any Monday morning and provides orientation in the operation and administration of a tissue bank. It includes (1) indoctrination in the methods of tissue procurement; (2) storage and dispensing; (3) tissue culture; (4) tissue chemistry; (5) processing excised tissue and allied short and long-term research projects in the tissue culture and tissue chemistry fields; (6) indoctrination in the medicolegal aspects of homotransplantation; (7) the procedure for obtaining permission for tissue donations; and (8) familiarization with the operation of the Tissue Bank Registry and all other administrative practices associated with tissue banking.

Reserve medical officers from the First, Third, Fourth, Fifth, Sixth, Eighth, and Ninth Naval Districts may attend this course on a limited quota basis authorized by the chief of naval personnel. Security clearance is not required.

Surgeon General Reappointed.—Rear Adm. Bartholomew W. Hogan was reappointed as surgeon general of the Navy for a period of two years, or until Feb. 15, 1961. He entered the service on June 6, 1925. In the early months of World War II, he served on the USS Wasp and was aboard that carrier when she was torpedoed in the South Pacific on Sept. 15, 1942. For heroic service during this action, he was awarded the Silver Star medal.

Personal.—Capt. A. J. Cerny has assumed command of the U. S. Naval Hospital, Guantanamo Bay, Cuba, relieving Capt. L. A. Newton, who retired on Jan. 31. Other medical officers retired were Captains F. V. Berley, M. J. Hantover (temporary disability), G. A. Gray, and H. L. Weaver.

VETERANS ADMINISTRATION

Treatment Centers for Mental Illness.—The first mental hygiene day center for treatment of veterans with service-connected mental illness was established at the VA outpatient clinic in Brooklyn, N. Y. More such clinics will be established within the next few years. The day center program is designed primarily to provide more and better outpatient treatment for the increasing number of veterans being released from VA hospitals after treatment for service-connected schizophrenia. Many of these patients need a great deal of help through the VA outpatient treatment program if they are to adjust to community living and avoid rehospitalization. The clinic director, Dr. Philip R. Casesa, said about 75 patients will spend the major part of their time at the new day center in a therapy and planned living program under the supervision of psychiatrists, psychologists, and social workers. In addition to individual and group psychotherapy and educational and occupational therapy, this program will include social and recreational activities carried out with the assistance of volunteers from the community. New tranquilizing drugs and improved treatment programs are increasing the number of patients, especially schizophrenics, being released from VA mental hospitals.

PUBLIC HEALTH SERVICE

Health Statistics.—A new report entitled "Hospitalization—Patients Discharged from Short-Stay Hospitals, July 1957-June 1958" has been published by the Public Health Service. For this report, the surveyed population consisted of the civilian noninstitutional population of the country. The data refer to persons in this population group who were discharged from the hospitals during the year. The short-stay hospitals include general, maternity, and other types in which most patients stay for less than 30 days. The number of patients discharged from such hospitals averaged 99.4 per 1,000 of the surveyed population. Among the group discharged, the average length of stay was 8.6 days. Next to childbirth, the most frequent cause of hospitalization was the respiratory diseases, including tonsil and adenoid conditions. The report is Public Health Service Publication no. 584-B7 and may be purchased from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., at 30 cents per copy.

Clinical Center Pamphlet Series.—The Clinical Center at the National Institutes of Health is publishing a series of pamphlets describing the methods and procedures used at the center. The first, "A Manual for Metabolic Balance Studies" by Marie M. Ceglarek, R.N., Bertha E. Bryant, R.N., and G. Donald Whedon, M.D. (PHS publication no. 607), is now available at 20 cents a copy from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C.

Personal.—Dr. William B. Sherman, associate attending physician of Presbyterian Hospital and attending physician at Roosevelt Hospital, New York City, and Dr. William W. Frye, professor of tropical medicine and dean of the school of medicine, Louisiana State University, New Orleans, have been appointed to the National Advisory Allergy and Infectious Diseases Council. They will advise and make recommendations to the surgeon general regarding research grants.

DEATHS

Anderson, Donald Carl Ⓜ West Palm Beach, Fla.; University of Minnesota Medical School, Minneapolis, 1945; interned at the Naval Hospital in San Diego, Calif.; veteran of World War II and Korean War; died Dec. 8, aged 41.

Ard, Robert Wilson Ⓜ Hagerstown, Md.; Syracuse University College of Medicine, 1948; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; resigned from the regular Navy on March 6, 1953; served in the U. S. Public Health Service Reserve; veteran of World War II and Korean War; died Dec. 20, aged 34.

Arneberg, John Gyro, Grand Forks, N. D.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; associated with Grand Forks Deaconess Hospital and St. Michael's Hospital; died Dec. 17, aged 83.

Audet, Louis Eugene Ⓜ Williamsport, Pa.; Tufts College Medical School, Boston, 1930; died in the Divine Providence Hospital Dec. 19, aged 54.

Bachman, David Floyd Ⓜ Bethlehem, Pa.; Medico-Chirurgical College of Philadelphia, 1912; formerly county coroner; died in St. Luke's Hospital Dec. 22, aged 74.

Barrow, John Vincent Ⓜ Los Angeles; Rush Medical College, Chicago, 1911; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the faculties of the College of Medical Evangelists in Loma Linda and Los Angeles and the Medical Department of the University of Southern California; past-president and vice-president of the Los Angeles County Medical Association, of which he was a councilor; served on the staffs of the California, Los Angeles County, and St. Vincent's hospitals, and the Hospital of the Good Samaritan; died Dec. 17, aged 81.

Batory, Roman Julius Ⓜ Stroudsburg, Pa.; Hahnemann Medical College of Philadelphia, 1930; interned at Women's Homeopathic Hospital in Philadelphia, where he served a residency; served a residency at Hamburg State Sanatorium for Tuberculosis in Hamburg; veteran of World War II; member of the American College of Chest Physicians; on the staff of the General Hospital of Monroe County in East Stroudsburg; died Dec. 21, aged 55.

Blumenschein, John Charles Ⓜ Independence, Mo.; Washington University School of Medicine, St. Louis, 1943; interned at Virginia Mason Hospital in Seattle; served a residency at St. Joseph Infirmary in Atlanta, Ga.; associated with the Independence Sanitarium and Hospital; died in Mogate, Honduras, Central America, Dec. 14, aged 40.

Blydenburgh, George Dean, Byesville, Ohio; University of Cincinnati College of Medicine, 1946; interned at White Cross Hospital in Columbus, Ohio; formerly an officer in the medical corps, Army of the United States; died in Columbus Dec. 28, aged 37.

Booth, George Randolph Ⓜ Wilburton, Okla.; Memphis (Tenn.) Hospital Medical College, 1904; died in the McAlester (Okla.) Hospital Dec. 14, aged 74.

Bowles, James Puryear Ⓜ Captain, U. S. Navy, retired, Richmond, Va.; Medical College of Virginia, Richmond, 1911; entered the U. S. Navy Jan. 24, 1921, and retired March 1, 1947; died in the U. S. Naval Hospital Philadelphia, Dec. 24, aged 73.

Breckwedel, Harry Benjamin, Newport Beach, Calif.; Columbia University College of Physicians and Surgeons, New York City, 1900; died Dec. 18, aged 85.

Cannon, Vern Edward, Decatur, Ill.; Chicago College of Medicine and Surgery, 1914; veteran of World War I; on the staff of St. Mary's Hospital; died Jan. 6, aged 68.

Catto, William Bruce Ⓜ El Reno, Okla.; University of Louisville (Ky.) Medical Department, 1908; on the staff of the Park View Hospital; died in Oklahoma City Dec. 7, aged 75.

Cloutier, Doria Marie, Albuquerque, N. M.; University of Wisconsin Medical School, Madison, 1950; died in the Bernalillo County–Indian Hospital Dec. 17, aged 36.

Cochran, J. Lawrence Ⓜ Carroll, Iowa; University of Tennessee College of Medicine, Memphis, 1931; veteran of World War II; president of the Carroll County Medical Society; county coroner; secretary-treasurer of the Iowa Coroners Association; member of the Aero Medical Association; associated with St. Anthony's Hospital, where he died Dec. 24, aged 50.

Coulter, William James, Toledo, Ohio; Toledo Medical College, 1900; served as a member of the staff of the Toledo Hospital; died Dec. 10, aged 91.

Ⓜ Indicates Member of the American Medical Association.

Crounse, Kenneth Eugene Ⓜ Albany, N. Y.; Albany Medical College, 1924; veteran of World War I; formerly on the faculty of his alma mater; consultant, Moses-Ludington Hospital in Ticonderoga; died in Delray Beach, Fla., Dec. 26, aged 61.

Darrin, Charles Bennett, Seattle; Bellevue Hospital Medical College, New York City, 1887; died in the King County Hospital, Harborview Dec. 3, aged 94.

Decker, Elmer Raymond Ⓜ Sunbury, Pa.; Medico-Chirurgical College of Philadelphia, 1910; veteran of World War I; consultant at Federal Penitentiary at Lewisburg; on the staff of the Evangelical Community Hospital in Lewisburg, where he died Dec. 27, aged 73.

Dreibrodt, Ben Allen Ⓜ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1938; veteran of World War II; on the staffs of St. Benedict's, Santa Rosa, and Baptist Memorial hospitals; died in the Robert B. Green Hospital Dec. 22, aged 45.

Fialk, Harry Ⓜ Union City, N. J.; Tulane University School of Medicine, New Orleans, 1929; fellow of the American College of Surgeons; veteran of World War II; on the staffs of the North Hudson Hospital in Weehawken, and the Medical Arts Center Hospital in New York City, where he died Dec. 27, aged 54.

Godfrey, Lincoln Jr. Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1942; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; research director of the National Council on Alcoholism; veteran of World War II; served on the faculty of his alma mater; on the staff of the Presbyterian Hospital; died Dec. 18, aged 43.

Green, Hyman Ⓜ Boston; Harvard Medical School, Boston, 1914; joined the British Expeditionary Forces in World War I and transferred later, as a captain, to the U. S. Army; member of the American Academy of Pediatrics; past-president of the Greater Boston Medical Association, New England Pediatric Society, and the Children's Hospital Alumni Association; associated with Children's and Beth Israel hospitals; died in the Veterans Administration Hospital Dec. 27, aged 68.

Grimes, Ivison, Camden, Texas; University of Tennessee College of Medicine, Memphis, 1914; died Dec. 11, aged 67.

Haight, Vincent Wymand Ⓜ Buchanan, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1919; veteran of World War I; an examining physician for the Metropolitan Life Insurance Company; since 1923 school physician of Central School District No. 3, town of Cortlandt; served as health officer for the village of Buchanan; on the staff of the Peekskill (N. Y.) Hospital; died in the Memorial Hospital, New York City, Dec. 7, aged 63.

Healey, Edward Joseph Gerard Ⓜ Weston, Mass.; Tufts College Medical School, Boston, 1943; veteran of World War II; certified by the National Board of Medical Examiners; specialist certified by the American Board of Radiology, Inc.; member of the American College of Radiology; radiologist at Waltham (Mass.) Hospital; associate radiologist at the Boston City Hospital; died in St. Elizabeth's Hospital, Boston, Dec. 13, aged 39.

Moet, Joe Louis Ⓜ La Feria, Texas; Baylor University College of Medicine, Dallas, 1941; veteran of World War II; a past-president of the Cameron-Willacy Counties Medical Society; member of the American Academy of General Practice; a member of the school board for the La Feria Independent School District; at one time chief of staff of Valley Baptist Hospital at Harlingen; died Oct. 20, aged 42.

Moore, Neil S. Ⓜ St. Louis; St. Louis University School of Medicine, 1913; on the faculty of his alma mater; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; past-president of St. Louis Medical Society; on the staffs of St. Louis County Hospital in Clayton, St. Anthony's Hospital, and Alexian Brothers Hospital; died Dec. 5, aged 71.

Moreland, James Thaddeus, Idabel, Okla.; Chattanooga (Tenn.) Medical College, 1901; veteran of World War I; died Nov. 22, aged 87.

Nauss, Ralph Welty, Gainesville, Fla.; Northwestern University Medical School, Chicago, 1905; formerly on the faculty of Cornell University Medical College in New York City, where he was on the staff of the New York Hospital; spent three years in the medical mission field in Belgian Congo; author of "Medical Parasitology and Zoology"; died in the University of Florida Infirmary Dec. 15, aged 82.

Northrup, John Fredrick Ⓜ Topeka, Kan.; College of Homeopathic Medicine and Surgery of the Kansas City University, Kansas City, Mo., 1899; died in the Stormont-Vail Hospital, Dec. 7, aged 83.

Owen, Harbert Claude Ⓜ Holly Bluff, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; died in the King's Daughters' Hospital, Yazoo City, Dec. 21, aged 80.

Plaut, Clarence Theodore Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1926; on the staff of the Jackson Park Hospital, where he died Jan. 5, aged 57.

Pontius, Guy Victor Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1923; associate professor of surgery at Northwestern University Medical School; on the staffs of the St. Francis Hospital in Blue Island, St. Luke's Hospital, and Illinois Central Hospital; died Jan. 4, aged 61.

Price, Oscar Jay Ⓜ Somerville, Mass.; Tufts College Medical School, Boston, 1901; for 40 years medical examiner for Metropolitan Life and Prudential Insurance companies; died in the Somerville Hospital Dec. 9, aged 84.

Rife, Dwight William Ⓜ Farmington, N. M.; University of Illinois College of Medicine, Chicago, 1931; interned at the Lutheran Deaconess Home and Hospital in Chicago; veteran of World War I; commander in the U. S. Naval Reserve during World War II and was in the invasion of Okinawa, receiving the Bronze Star as a result of his performance at that time; died Dec. 21, aged 62.

Rock, Thomas Stephen Ⓜ Lancaster, N. H.; Columbia University College of Physicians and Surgeons, New York City, 1947; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; member of the staff and chief of surgery at Beatrice Weeks Memorial Hospital; formerly associated with the Veterans Administration Hospital, White River Junction, Vt.; died in the Mary Hitchcock Hospital, Hanover, Nov. 27, aged 36.

Sachs, Ernest Ⓜ North Haven, Conn.; born in New York City Jan. 25, 1879; Johns Hopkins University School of Medicine, Baltimore, 1904; on the faculty of Yale University School of Medicine in New Haven; professor emeritus of neurological surgery at Washington University School of Medicine in St. Louis, where he was on the staffs of the Ellis Fischel State Cancer Hospital in Columbia, Barnes, St. Louis Children's, St. Louis Maternity, and St. Louis City hospitals; past-president of the American Neurological Association; past-president and secretary of the Society of Neurological Surgeons; member of the Southern Surgical Association, American Physiological Association, St. Louis Surgical Society, Sigma Xi, and Phi Beta Pi; fellow of the American College of Surgeons and the International College of Surgeons; member of the founders group of the American Board of Surgery; specialist certified by the American Board of Neurological Surgery; author of many books; died in the Grace–New Haven Memorial Hospital in New Haven Dec. 2, aged 79.

Schloss, Max Ⓜ Jackson Heights, N. Y.; Ludwig–Maximilians–Universität Medizinische Fakultät, Munchen, Bavaria, Germany, 1924; member of the American Society of Anesthesiologists; died in New York City Nov. 20, aged 60.

Schussler, Edward G. Ⓜ Oaklawn, Ill.; Chicago College of Medicine and Surgery, 1908; associated with Little Company of Mary Hospital in Evergreen Park and the South Chicago Community Hospital in Chicago; died in Chicago Dec. 16, aged 72.

Scibetta, Louis Joseph, Erie, Pa.; Detroit College of Medicine and Surgery, 1928; an associate member of the American Medical Association; died in St. Vincent's Hospital Dec. 17, aged 58.

Segal, Marek M. Ⓜ New York City; Uniwersytet Jozefa Pilsudskiégo, Warszawa, Poland, 1924; associated with the Hospital for Joint Diseases; died in Lake Mahopac, N. Y., Dec. 7, aged 60.

Shoun, Alexander Nelson Ⓜ San Manuel, Ariz.; Jefferson Medical College of Philadelphia, 1932; member of the American Rheumatism Association; president of the Pinal County Medical Society; formerly practiced in Winston–Salem, N. C., where he was school physician with the city department of health; associated with the San Manuel Cooper Corporation Hospital; died Dec. 12, aged 51.

Smith, Clarence B., Roff, Okla.; University of Texas School of Medicine, Galveston, 1899; died in the Valley View Hospital in Ada Dec. 2, aged 82.

Smith, Edward Greer Ⓜ Mercedes, Texas; Dallas Medical College, 1904; for 32 years served the Missouri–Pacific Railroad as local physician; died Dec. 10, aged 86.

Stanka, Andrew George Ⓜ Grand Ledge, Mich.; University of Michigan Department of Medicine and Surgery, Minneapolis, 1909; member of the American Academy of General Practice; served on the staff of the St. Lawrence Hospital in Lansing; died Dec. 13, aged 79.

Strecker, Edward Adam, Philadelphia; born in Philadelphia Oct. 16, 1886; Jefferson Medical College of Philadelphia, 1911; named professor of nervous and mental diseases at his alma mater in 1925, serving until 1931, and in that year became professor and head of the department of psychiatry at the University of Pennsylvania School of Medicine, where he remained in that capacity until he became professor emeritus in 1953; emeritus professor of psychiatry at the University of Pennsylvania Graduate School of Medicine; clinical professor of psychiatry and mental diseases at Yale University in New Haven, Conn., from 1926 to 1932; appointed as the first professor of psychiatry at the Seton Hall College of Medicine and Dentistry, Jersey City; in 1939 was selected to deliver the Salmon Lectures on psychiatry and mental hygiene; gave the Pasteur, Menas Gregory Memorial, and Bernard McGhie Memorial lectures in 1946; specialist certified by the American Board of

Psychiatry and Neurology; an associate member of the American Medical Association; member and past-president of the American Psychiatric Association; member and formerly vice-president of the American Neurological Association; member of the American Psychosomatic Society, the Association for Research in Nervous and Mental Diseases, Alpha Omega Alpha, Sigma Phi Epsilon, and Alpha Kappa Kappa; fellow of the American College of Physicians; on May 24, 1944, received the Dr. I. P. Strittmatter Award of the Philadelphia County Medical Society "in recognition of his distinguished service in the field of psychiatry and mental hygiene and his unselfish devotion to the highest ideals of the profession as physician, teacher, author and consultant in civilian and military medicine"; during World War I held the rank of major in the medical corps of the U. S. Army, as division neuropsychiatrist for the 28th division in France; during World War II named special consultant to the Secretary of War for the Air Forces of the U. S. Army; on Jan. 16, 1948, was awarded the Presidential Certificate of Merit in recognition of his services as consultant to the Surgeon General of the Navy since May 6, 1943; the new building at the New Jersey Neuro-Psychiatric Institute, Princeton, dedicated in 1957 was named after him; since 1917 medical and clinical director of the Pennsylvania Hospital Department for Mental and Nervous Diseases; served as chief of service and consultant at the Institute for Mental Hygiene at Pennsylvania Hospital, consultant to the U. S. Public Health Service, to Bryn Mawr College, and to the U. S. Veterans Bureau; author of more than 200 published papers and several books on psychiatry; died in the Jefferson Medical College Hospital Jan. 2, aged 72.

Tanner, Kirby, Covington, Ky.; Medical College of Ohio, Cincinnati, 1900; died in the Kenton County Infirmary Nov. 8, aged 85.

Thiery, Raymond Donle Ⓜ South Bridgewater, Mass.; Harvard Medical School, Boston, 1923; died in St. Luke's Hospital, Middleboro, Nov. 26, aged 62.

Thompson, Clara Mabel, New York City; Johns Hopkins University School of Medicine, Baltimore, 1920; member of the Medical Society of the State of New York, American Psychoanalytic Association, American Psychosomatic Society, American Psychiatric Association, and the American Psychopathological Association; served as vice-president of the Association for the Advancement of Psychoanalysis; formerly on the faculty of the New York Medical College, Flower and Fifth Avenue Hospitals, and her alma mater; executive director of the William Alanson White Institute of Psychiatry, Psychoanalysis and Psychology; died Dec. 20, aged 65.

Turner, Oliver William Ⓜ Boothbay Harbor, Maine; Jefferson Medical College of Philadelphia, 1893; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly on the staffs of the Augusta General and Augusta State hospitals in Augusta; died in Jackson Heights, N. Y., Nov. 24, aged 90.

Van Horne, Thomas Calvin, Pittsburgh; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1903; an associate member of the American Medical Association; died Dec. 7, aged 83.

Van Tromp, Homer Ovid, Buckhannon, W. Va.; Eclectic Medical College, Omaha, 1913; an associate member of the American Medical Association; past-president and secretary of the Central West Virginia Medical Society; formerly assistant superintendent and clinical director of Weston (W. Va.) State Hospital, where for one year he was acting superintendent; died Dec. 16, aged 81.

Walch, Joseph Francis Ⓜ Lawrence, Mass.; Tufts College Medical School, Boston, 1904; charter member and medical director of the Lawrence Tuberculosis Association; in 1956 awarded a plaque by the Greater Lawrence Tuberculosis Association for his services as medical advisor since 1912; on the staffs of the Clover Hill Hospital, Lawrence General Hospital, and McGowan Memorial Hospital; died Dec. 5, aged 85.

Wapstra, Ilse Sigrid Ⓜ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1931; died Dec. 29, aged 53.

Ward, William Trulock Ⓜ Salt Lake City; Columbia University College of Physicians and Surgeons, New York City, 1908; for many years on the staff of the Holy Cross Hospital; a member of the board of directors of the First Federal Savings and Loan Association; died Dec. 10, aged 78.

Williams, William Lee, Florence, S. C.; Meharry Medical College, Nashville, Tenn., 1915; died Oct. 1, aged 57.

Willis, James Clinton Jr. Ⓜ Shreveport, La.; Tulane University School of Medicine, New Orleans, 1916; fellow of the American College of Surgeons; president of the Willis-Knighton Memorial Hospital; chairman of the board of directors of Louisiana Bank and Trust Company; senior surgeon for the Illinois Central Railroad; died Dec. 14, aged 67.

Wingquist, Carl Gustave, Crosby, Minn.; University of Minnesota Medical School, Minneapolis, 1932; veteran of World War II; on the staff of the Miners' Hospital, where he died Nov. 4, aged 53.

Wright, Oren Henry Ⓜ Chicago; Rush Medical College, Chicago, 1912; died Dec. 30, aged 73.

FOREIGN LETTERS

AUSTRIA

Operations on the Mentally Ill.—At the meeting of the Society of Physicians in Vienna on Jan. 9, Drs. E. Ringel and H. Schinko stated that a physician is authorized to operate on a patient without the patient's consent if the patient's life is in danger, as in rupture of the stomach. Should the physician establish the diagnosis of a cancer, the operation would also be considered "vitally indicated" inasmuch as the life of the patient is threatened if he is not operated on, but in this case consent of the patient is absolutely necessary. This consent may not be given, however, by a patient with organic dementia, involutional melancholia, amentia, and some types of severe neurosis. Sufficient improvement of the mental disorders, with the exception of some forms of dementia, can be expected today with suitable therapy so that the patient may consent to operation. This year nine patients who had not consented to operation did so after they had been treated at the university neuropsychiatric clinic. These patients are in a good physical and mental condition today. This solution is preferred to operation without the consent of the patient even when he is mentally ill. As to patients with neurosis, the speakers emphasized that their tendency to self-injury may manifest itself in a rejection of an operation or by urging the surgeon to perform an unnecessary operation. In the first instance the psychiatrist should try to persuade the patient to see the surgeon, and in the second instance the surgeon should send the patient to the psychiatrist.

Shorter Hours Requested for Physicians.—The Federal Branch Group of Hospital Physicians have requested shorter hours similar to those already approved for many other professional groups. In letters which were mailed to various hospital managers, attention was called to the enormous work load which has been placed on the hospital physicians and the following demands were listed: (1) a 45-hour week for those hospital physicians who perform their services according to service-agreements with a fixed time of service (up to now, a 48-hour week) in accident-hospitals and in institutions of the District Sick Insurance Funds, (2) every other Saturday off duty, and (3) in hospitals in which, for medical or administrative reasons, a free Saturday every second week cannot be granted, a 10% increase in basic salary.

CANADA

Paralysis Agitans.—DeJong (*Canad. Serv. M. J.* 14:695, 1958) called attention to the difficulty of defining paralysis agitans. Neither the anatomic definition as a disease of the substantia nigra nor the physiological definition as a disorder of the extrapyramidal system is satisfactory. The average physician probably diagnoses the condition on evidence of muscle rigidity and tremor of the limbs, which means that some patients with pulmonary complications due to rigidity of the chest wall or others with neurogenic bladder may not be recorded correctly, and absence of classic features may further diminish the recorded incidence. Canadian Sickness Survey figures suggest a general morbidity for the population of 0.30 per 1,000, rising to 0.85 for the age group from 45 to 64 and 1.52 for those over 65 years of age. DeJong believes that the incidence quoted for the United States of 1,000,000 to 1,500,000 cases is way out of line with Canadian figures. The death rate in Canada for this disease from 1931 to 1956 ranged widely, from 1.42 to 2.49 per 1,000—probably a reflection of the difficulty of accurate diagnosis and recording.

Unlawful Practice Charge.—A charge brought in Ontario of unlawful practice of medicine received a great deal of unfortunate publicity in the press, and the situation was not entirely clarified until the recent publication of an official letter from the provincial College of Physicians and Surgeons in the *Ontario Medical Review*. An English physician was engaged by the Canadian Department of Indian Affairs to treat Indians on an Ontario reservation. For this purpose it was not required that he be licensed in the province (a step which would have involved an internship and examination), provided he treated only Indians of the reservation. Information received by the provincial licensing body indicated that the physician was attending private patients, in spite of a warning to desist, and charging fees. An inspector from the licensing body visited the doctor alleging certain symptoms, received treatment, and was charged $5 for which he was given a receipt on an official government form. A charge was then laid by the inspector of "professing to practice medicine while unregistered under the Ontario Medical Act."

When the case came to court, the Department of Indian Affairs provided defense counsel and one of their officials gave evidence that there was an

The items in these letters are contributed by regular correspondents in the various foreign countries.

agreement with local physicians, who were overworked, that the government physician could see patients in an emergency and hand over his fees to the government, which this physician had scrupulously done. The magistrate dismissed the charge. In the official statement from the licensing body, the letter indicated that it would not appeal the decision, on the grounds that the case is not of sufficient importance and that its proper function is to place evidence before a court rather than to strive for conviction of the person charged.

Thermal Responses to Drugs.—Medical literature contains confusing reports of the effects of some drugs on body temperature. For instance, it has been suggested that ergot may cause hypothermia, hyperthermia, or no change in body temperature. Shemano and Nickerson (*Canad. J. Biochem. & Physiol.* 36:1243, 1958) have clarified this situation with some experiments on rats given drugs at various ambient temperatures. The drugs investigated included chlorpromazine, ergotamine, Hydergine, *d*-lysergic acid diethylamide (LSD 25), serotonin, and reserpine. They were injected subcutaneously with subsequent hourly recording of the colonic temperature. The room temperature was varied and it was shown that chlorpromazine produced hypothermia at ambient temperatures of 30 to 33 C, no significant effect at 36 C, and hyperthermia at 39 C. Similarly, Hydergine, ergotamine, serotonin, and LSD 25 all caused hypothermia at 25 C and hyperthermia at 33 C. Reserpine caused hypothermia at lower temperatures but no consistent effect at higher ones, and dinitrophenol, a drug usually thought to have a peripheral action on body temperature, followed the pattern of the others. Hence, in assessing the action of a drug on body temperature, it must be realized that there may be a critical ambient temperature at which the effect is reversed. The agents studied appear to interfere with central body temperature regulation.

Tissue Committees.—A recent symposium, reported in *Canadian Doctor* (24:29, 1958) without naming the participants, dealt with the question of whether the hospital tissue committee is worth while. The two basic objectives of such committees are the preservation of the integrity of the medical profession and the protection of patients against needless operations. Such committees lack jurisdiction and are strictly fact-finding bodies giving information to the hospital staff. The gynecologist and the surgeon contributing to the symposium agreed that the committee was necessary in smaller hospitals lacking the censorship imposed by the presence of interns, residents, students, and department heads and thought that its presence also made for a more careful recording of cases. It might also be of value where a colleague was in difficulties because of emotional instability, illness, or too great responsibility. The pathologist urged that evaluation of cases should take place within a matter of hours and that surgeons should not be criticized because of the committee's low rating on a specific type of case. The only value of the statistics was to show comparative trends. The lawyer warned of the legal hazards of condemnation of a surgeon's work by a tissue committee. In a malpractice suit a client's lawyer would be in a strong position if he were aware of such condemnation, and since the tissue committee's reports were hospital documents, they could be subpoenaed. The surgeon should have a chance of explaining to the committee the factors that influenced his decision to operate.

Death Rates and Living Standards.—Metropolitan Life Insurance Company figures show that the death rate in Canada for 1958 was the lowest on record—about 8 per 1,000. This decrease in the death rate reflects in large measure the lower incidence of respiratory diseases and to some extent the lower mortality from chronic diseases in elderly people. Cardiovascular and childhood diseases had a lower rate, and the rate for cancer and motor accidents remained about the same as in 1957. The Salk vaccine helped to reduce the number of poliomyelitis cases to fewer than 300 (mostly in Manitoba) as against 9,000 in 1953. However, as a correspondent in *Canadian Doctor* pointed out, the age-adjusted death rates in both Canada and the United States were higher than in Norway, the Netherlands, and Denmark for males, and the Netherlands and Sweden for females. This correspondent speculated on the paradox that the two countries with the highest standards of living in the world do not keep their citizens alive to enjoy it for as long as persons in slightly less favored countries.

Imipramine in Depressions.—Imipramine or N-3′-dimethylaminopropyl-iminodibenzyl hydrochloride was used to treat 84 patients with dysphoric depression at Verdun Psychiatric Hospital, Quebec, by Lehmann and co-workers (*Canad. Psychiat. A. J.* 3:155, 1958). Their results were roughly comparable to those reported by Kuhn (Switzerland), namely recovery or marked improvement in 30% after two weeks' therapy, and in 60% after eight weeks' therapy. The results were less favorable in patients who had depression associated with neuroses, schizophrenia, or organic conditions than in those with endogenous depression. The dosage usually began at 100 mg. daily by mouth or intramuscularly (both were equally effective) and was increased after a few days to 150 mg. and in a large percentage to from 200 to 600 mg. The incidence of side-effects increased with doses over 200 mg. a day, especially in patients over 65 years of age. The main one was disturbance of autonomic nervous system function, but there were a few cases of toxic confusion, two of epilepsy, and one of mild jaundice.

Acute Alcoholism.—Kofman and co-workers (*Canad. M. A. J.* 79:988, 1958) compared the results of treating 500 patients in a state of acute alcoholic intoxication by giving insulin and dextrose intravenously with those in 163 treated with reserpine and 114 treated with perphenazine. Only a few in the series had delirium tremens. Reserpine was given intramuscularly in 2.5-mg. doses on admission and after one hour and then routinely in six hours, with further doses if the patient remained unsettled. An initial dose of 10 mg. of perphenazine was given intramuscularly and repeated after one hour with subsequent 5-mg. doses as needed. Both reserpine and perphenazine were more effective than the insulin-dextrose regimen, and perphenazine was considered the most effective and least complex agent these workers had used in treating acute alcoholism.

FINLAND

Corticosteroid-Produced Peptic Ulcers.—Heino Laitinen, and co-workers (*Acta rheumatol. scandinav.* 4:205-217, 1958) reported a series of 15 patients with peptic ulcers occurring during corticosteroid therapy which were characterized by a location near the pylorus; large, deep, and often penetrating ulcer niches; mild clinical symptoms; good clinical and roentgenologic healing, even in 7 patients in whom corticosteroid therapy was continued; and absence of late complications, which are not unusual in connection with ulcers at or near the pylorus. The follow-up period was over one year in eight cases, and four years in one. During this time examinations showed an apparently permanent healing. The roentgenograms disclosed either normal conditions or minimal bulbar deformity. Pyloric stenosis, which frequently results from a juxtapyloric ulcer, was not encountered in any of these patients.

Mast Cells in the Gastric Mucosa.—The mast cell count was determined in specimens taken from the fundus of the stomach by the suction biopsy method and reported on by Siurala and Sundberg (*Ann. med. exper. et biol. Fenniae* 36:271-277, 1958). The mean mast cell count in 17 persons with a normal gastric mucosa was 79 ± 8.6. In 8 patients with superficial gastritis it was 125 ± 24.1; in 21 with slight atrophic gastritis it was 153 ± 18.3; and in 11 with severe atrophic gastritis it was 150 ± 13.7. The difference in the mast cell count of a normal and atrophic mucosa was statistically significant. There was also some correlation between the mast cell count and the degree of inflammatory changes. It could not be demonstrated that the age of the patient or the severity of the disease had any definite influence on the mast cell count of the gastric mucosa.

Asian Influenza.—Ohela and Kaipainen (*Nord. med.* 60:1700-1701, Nov. 27, 1958) reported that the Asian influenza epidemic was well started in Finland by the end of September, 1957, but by December the number of new cases began to decrease. The total number of cases was estimated to be at least 700,000. Of the 1,322 persons who died in the epidemic, influenza was the sole cause of death in 478 and in the rest one or more additional diseases were involved. A large proportion of the fatal cases were in patients under 5 and over 65 years of age.

FRANCE

Tomography of the Prostate.—Sichel and Blum (*Journal de radiologie, d'électrologie et de médecine nucléaire*, September, 1958) made tomograms of the prostate by taking negatives at depth intervals of 0.5 to 1 cm. If an adenoma is present, its volume and outline can be determined. In case of cancer, the appearance of the dome of the tumor resembles that of the adenoma but is of greater density.

Deaths from Chloramphenicol.—Lamy and coworkers presented to the Académie Nationale de Médecine a series of three cases of fatal purpura hemorrhagia in children who were given small repeated doses of chloramphenicol. They developed a severe thrombopenia against which corticotherapy was of no avail. The authors believe that the small repeated doses caused the development of an allergic phenomenon. They suggested that unless strong indications exist chloramphenicol should not be prescribed.

Humoral Study of Psychopaths.—G. Sandor and C. Chatagnon studied the serums of 230 psychopathic female patients and reported their results at a meeting of the Académie Nationale de Médecine. Of 43 patients with organic lesions, 11 had a normal serum and 22 had hyper-alpha-globulinemia. The findings in 56 patients with acute depression but no organic lesions were similar. In 24 mentally defective subjects, on the other hand, hyper-alpha-globulinemia was rare but 12 of them had hyper-gamma-globulinemia. The findings in 54 schizophrenics were similar. The authors contrasted the two groups—patients with the organic psychopathy and those with acute depression showing an increase in psychic tension and schizophrenics and mental defectives showing a decrease in this tension. They believed that this tension is associated with a hormonal secretion, which modifies the protein composition of the serum. The neurohormonal action of the anterior lobe of the pituitary may play a part in the production of hyper-gammaglobulinemia, when the nervous tension falls. Gleye and Sandor showed that epinephrine produced in guinea pigs a marked hyper-alpha-globulinemia. It is therefore possible that psychic tension may provoke the secretion of the adrenal medulla.

NORWAY

Primary Dislocation of the Patella.—As a plea for operative instead of conservative treatment for primary dislocation of the patella, Dr. Y. Kjelstrup (*Nordisk medicin,* Dec. 18, 1958) gave an account of nine such patients operated on by him. Serving as informal controls were six patients who, in the same period, had a history of an earlier dislocation of the patella for which no operation had been performed. All of them were much embarrassed by their knees, which in two cases presented marginal fractures. Of the nine primary cases six patients were under 18. Six of the patients came to the hospital with the injured knee flexed and the patella displaced inwards. On operation, inspection of the joint revealed nothing amiss with it apart from the patella and its attachments. The lesions were varied but more or less rupture of the attachment of the vastus medialis tendon was common to all. After suture of the torn structures the knee was slightly immobilized by a bandage which allowed daily inspection and control of the knee. After about a fortnight, movements were permitted, and after three weeks, walking with crutches. With one exception a complete return to normal was achieved.

Nilatil for Angina Pectoris.—At the Aker and Ullevaal hospitals in Oslo, trials were made with nilatil (amino-ethyl-nitrate-p-toluol-sulfonate) in 58 patients who had angina pectoris. Rörvik and Selvaag (*Tidsskrift for den norske lægeforening,* Dec. 15, 1958) reported that this drug is slower to take effect than nitroglycerine, but its action lasts longer—at least two hours. It reduces the systolic blood pressure by 15 to 20 mm. Hg, and its administration can be sublingual or peroral. It is easily soluble in water, and it keeps well for at least a year in tablet form or solution. Within 10 to 15 minutes it provokes a sense of heat and throbbing in the head and, if the dose is big enough, a headache. This headache was the only important side-effect, and it was taken as a therapeutic guide, pushing the dose up to a point just short of the headache level. The usual dosage was one 2-mg. tablet three or four times a day. Headache was a guide to a reduction of the dosage, but there were only two patients in whom headache led to discontinuation of this treatment. As excellent or marked relief of symptoms was obtained in about 67% of their patients, the authors concluded that nilatil was the best slow-acting nitrate derivative available for angina pectoris.

Asian Influenza.—Dr. A. Harboe of the Influenza Laboratory of the State Institute for National Health in Oslo (*Nordisk medicin,* Nov. 27, 1958) reported that the outbreak of Asian influenza started in Rjukan, a small inland town, towards the end of August, 1957. Samples received by his laboratory on Sept. 9 were the first to contain the causative virus. In the middle of September there was an intense outbreak of the disease in army concentrations in Stavanger, and in the course of the next fortnight it spread to most of the military centers in southern Norway. Ultimately the whole of Norway was involved, and 19 different strains were cultivated. The major wave, involving the whole country in the first half of October, was followed by a second wave in Oslo at Christmas. School children and the personnel of military camps showed a particularly high morbidity, and in a camp of 223 recruits 88% were found to have developed antibodies to the virus. In the adult general population in Oslo, the incidence of influenza was between 10 and 15%. After isolation and typing, the different strains were sent to the World Influenza Center in London where they were identified as belonging to the Asian type. In Norway no difference could be found between the Norwegian strains and the prototype Singapore strain in respect to their antigenic properties. Vaccine imported from Denmark and Holland was used in the isolation departments of the larger hospitals. It was calculated that at Oslo's City Hospital vaccination had reduced the number of cases by 50% and the number of sickness days by 60%.

Enuresis.—A note of disillusion over the hospital treatment of nocturnal enuresis was struck by Rinvik and Steel (*Tidsskrift for den norske lægeforening,* Dec. 15, 1958) who treated 186 patients with this condition in a children's hospital. A questionnaire addressed to the parents after discharge from the hospital yielded answers from 122. They showed that a recovery could be claimed in 20%, and some improvement in 17%, whereas in the remaining 63% the enuresis persisted one to six years after discharge. Little use was made of drugs in the hospital where the children were awakened once nightly to empty their bladders. One of the main arguments in favor of hospital treatment for enuresis was the opportunity it afforded for the discovery of organic and mental disease. Various tests were applied, including urography, which in 9 of the 158 patients thus examined showed abnormalities of the urinary tract. There were also 12 cases of men-
50% one or more members of the family also suf-
tal retardation. The 122 answers showed that in
fered from enuresis. The authors concluded that

little can be gained by admitting patients under 5 or 6 years to the hospital even though organic disease can thereby be detected earlier. They are skeptical about the value of reducing the water intake in the afternoon, for the children are quick to circumvent their nurses in this respect. As for drugs, tincture of belladonna continues to have its advocates, but it must be pushed if it is to be effective.

SWEDEN

Radical Pancreatic Surgery.—Erik Millbourn (*Acta chir. scandinav.* 116:1, 1958) performed a radical pancreatectomy on 15 patients with cancer of the head of the pancreas and 1 with cancer of the ampulla of Vater. There were three operative deaths, two of which occurred early in the series. Advanced age (over 70 years) in four patients was not considered a contraindication to this operation. Two patients including one with carcinoma of the ampulla of Vater survived almost four years. Two survived two and one-half years. Two patients felt well and had no signs of metastasis or recurrence when last seen three and one-half and two and one-half years, respectively, after the operation. One patient had a second operation, a pancreaticogastrostomy, in March, 1958, after which he had no evidence of metastasis or recurrence. The average survival time was 23 months. Radical pancreatectomy gave these patients their only chance of survival. The author recommended pancreaticoduodenal resection, combined with the necessary anastomosis, in patients with cancer of the head of the pancreas or of the ampulla of Vater, where local excision via a duodenotomy is not possible. He preferred pancreaticogastrostomy to pancreaticojejunostomy, and stated that total pancreaticoduodenectomy was to be avoided.

The author outlined a two-stage operation, the first stage consisting of cholecystojejunostomy and enteroanastomosis and the second stage, pancreaticoduodenal resection, pancreaticogastrostomy, choledochojejunostomy, and gastrojejunostomy. The gastrojejunostomy must be placed distally to the other anastomosis on the efferent loop. Most of the patients are thus provided with two sphincterless openings for the bile flow to the jejunum, a cholecystojejunostomy established in the first stage and a choledochojejunostomy in the second. The coexistence of the two sphincterless openings for bile flow into the jejunum does not as a rule produce postoperative complications. Of eight patients with two openings one had trouble postoperatively, probably due partly to the fact that one sphincterless opening is all that is necessary for the bile flow to the jejunum. One patient, who subsequently died of peritoneal carcinosis, had attacks of cholangitis in the last months of her life. In patients with carcinoma in the ampulla a biopsy specimen should be taken in the first stage through duodenotomy. In those with carcinoma of the head of the pancreas excision of tissue for biopsy is not always without danger. In addition, it is sometimes difficult for the surgeon to obtain a satisfactory biopsy specimen.

Treatment of Ureterolithiasis.—In 1956 Einar Sandegård analyzed a series of patients with ureteral stones treated expectantly and in *Acta chirurgica scandinavica* (116:52, 1958) he presented a follow-up examination of a similar series five years after the attack. Of these 94% were examined urographically. In the interval of between five and six years from onset to follow-up definite recurrences were found in 17% and probable or possible recurrences in 8%. The roentgenographic follow-up demonstrated a recurrence of renal calculi in only 4%. Thus, although ureteral recurrences were fairly common after ureterolithiasis, concretions were rarely found in the kidney. In all of 86 patients treated conservatively, follow-up urography showed the excretory function of the kidneys to be normal. In 29 treated with active procedures, appreciable renal damage had been present prior to operation in 3 but the remaining 26 showed normal kidney function on urographic follow-up examination. No new lesions such as dilatation of the ureter or renal pelvis were noted.

Combined Tetanus Prophylaxis.—The effect of combined active-passive prophylaxis against tetanus was compared by Bergentz and Philipson (*Acta chir. scandinav.* 116:58-67, 1958) with that of solely passive and solely active immunization by determining the serum antitoxin concentrations in military recruits at different periods after immunization. The effect of a booster dose was compared in the same way in the groups treated with active and combined immunization respectively. The results on 22 subjects with passive immunization only, 19 with combined simultaneous active-passive immunization, and 20 with active immunization only led to the following conclusions: The passive immunity secured by combined treatment was slightly lower than that of passive treatment. Of those immunized passively 60% had titers above 0.2 immunizing units (IU) per milliliter but only 15% of the simultaneously immunized had titers above that level. Corresponding values for the 0.1 IU per milliliter–level were 86 and 68% respectively. Measurable antitoxin concentrations corresponding to active immunity in the serums of those treated with simultaneous prophylaxis appeared later than in those actively immunized. A rise in antibodies was not detected until 45 to 74 days after injection in subjects receiving combined treatment while the rise in antibodies appeared between 14 and 24 days after injection in the group actively immunized. The effect of a booster dose was the same in the group immunized actively and in that treated with a combined injection.

Tennis Leg.—Tennis leg is a traumatic lesion of the calf which is generally believed to be due to a subcutaneous rupture of the plantaris muscle. Arner and Lindholm (*Acta chir. scandinav.* 116:73-75, 1958) questioned whether the signs and symptoms of tennis leg were caused by such a rupture. The location of the pain, the distinct tenderness and hematoma formation on the medial aspect of the calf midway between the heel and the knee, and the loss of power could not be accounted for by rupture of the plantaris muscle belly, its musculotendinous junction, or the tendon itself. Twenty patients with characteristic features of tennis leg were studied. A gap in the medial gastrocnemius belly roughly at the musculotendinous junction was observed in every instance. Surgical exploration in five verified the rupture of the gastrocnemius, while the plantaris tendon was found to be intact in all five. In all 20 patients the rupture was shown to occur on sudden dorsiflexion of a foot in supination and plantar flexion with the knee joint in extension. This combination of movements produces the greatest contraction of the medial gastrocnemius belly thereby exposing it to the greatest indirect violence with resultant rupture.

SWITZERLAND

Exports of Narcotics.—The permanent Central Opium Board (Geneva) drew attention in a report to the obligations of governments in connection with the export and import of dangerous narcotics. Specific reference was made to the West German production of normethadone, a narcotic described as being as dangerous as morphine, and used in such cough mixtures as Ticarda and Taurocolo. This drug is manufactured mainly in West Germany and has been under international control since November, 1954, although Bonn, not being a party to the 1948 protocol, has not exercised any control over it. The West German government failed to report its exports of normethadone for 1957 to the Central Opium Board, although there was evidence that in 1956 preparations of this narcotic had been exported to 56 countries 48 of which did not report the fact when questioned. Some of the governments concerned stated that the importation took place without their knowledge.

The Board blamed the failure to disclose this information on the governments concerned. It strongly recommended that, when any new product for which analgesic or antitussive properties are claimed is about to be marketed, the government of the country of manufacture should subject it to control measures until the World Health Organization has determined its liability to habit formation. The Board stated that the guiding principle in all such cases should be that commercial interests must yield to consideration of public health. After the issue of the Board's report it was stated that the Interior Ministry of West Germany would introduce further legislation for the control of narcotics. The Central Opium Board gave the following data on world narcotics production: In 1957 714 tons of raw opium were produced, less than the average annual production of 867 tons during the period from 1946 to 1957; morphine production was 109 tons, of which 94 tons was used for the manufacture of codeine and other derivatives. The consumption of morphine as such was only 4 tons. The production of codeine was 97 tons, an increase over previous years, of which 90 tons was consumed and the remainder converted into other derivatives.

Of the synthetic narcotics meperidine still leads the field with an annual consumption of 14 tons. The use of cocaine is declining. Annual consumption is now 1,619 kg., a reduction of nearly 400 kg. in three years. The consumption of methadone dropped from 750 kg. in 1954 to 464 kg. in 1957. The Board stated that North America continued to be one of the main destinations of illicit narcotic traffic, particularly in heroin. Much traffic in marijuana occurred in Africa, although attempts have been made to stamp it out in Egypt where several confiscations have been reported. An active illicit drug traffic, particularly in opium, morphine, heroin, and marijuana, occurred in the Near East. In the Far East illicit traffic in these narcotics continued in Hong Kong, Singapore, Malaya, Thailand, and China. There was also illicit opium traffic in Pakistan, India, and Iran.

UNITED KINGDOM

Maple Syrup Disease.—The first British case of a rare disease known as maple syrup disease was observed by Mackenzie and Woolf (*Brit. M. J.* 1:90, 1959). The condition is so called because the urine has the odor of maple syrup. The patient was a 4-month-old girl with anemia, lack of control of head movement, increased muscle tone and tendon reflexes, pallor of the optic disks, a low mentality, and an abnormal electroencephalogram. When the urine was examined to exclude phenylketonuria it was found to smell of maple syrup. On two-dimensional paper chromatography valine, leucine, and isoleucine were found in large amounts. They were also present in excess in the blood, spinal fluid, and saliva. The urine contained large quantities of keto acids and alpha-hydroxy acids, which were responsible for the smell of maple syrup. This was intensified by acidification with sulfuric acid. Further examination revealed the presence of large amounts of indolylacetic and indolyllactic acids. The fasting blood sugar level was only 52 mg. per 100 ml.

Another case was observed simultaneously in New York by Dancis and co-workers (*Brit. M. J.* 1:91, 1959). Maple syrup urine disease is an inborn error of metabolism, involving valine, leucine, and isoleucine and similar in some respects to phenylketonuria, for which it may be mistaken as results of the ferric chloride test are similar for both. In both conditions there is a disturbance of tryptophan metabolism as shown by the excretion of large quantities of indolylacetic and indolyllactic acids. Like phenylketonuria the condition is associated with progressive mental deterioration. Mackenzie and Woolf gave the child a diet low in valine, leucine, and isoleucine, but the mental deterioration was such that improvement was unlikely. They considered that the accumulation of abnormal metabolites, i. e., the hydroxy and keto acids, and the amino acid concentration in the blood were responsible for the mental defect.

Reasons for Shortage of Nurses.—British hospitals are finding it increasingly difficult to maintain a 24-hour nursing service. One difficulty is the provision of adequate night service. The Royal College of Nursing, reporting on the problem, deplored the practice in many hospitals of waking patients at 5 a. m. Because of this, night nurses are expected to do far too much work in the early hours of the morning, and in consequence they suffer from overfatigue and the quality of their work deteriorates. The anxiety associated with night duty causes many student nurses to abandon their careers. The report urged the reduction of night duty from 12 to 8 hours. Other recommendations were two meal breaks away from the wards and advance notice of nights off so that the nurses can join in the social life of the community. Junior nurses should not be left alone when seniors go to meals, and trained nurses should not have to undertake domestic and clerical duties as many of them do at present. Salaries should be adequate. The report recommends that nurses should not do more than two years of continuous night duty.

Air Pollution.—Stocks (*Brit. M. J.* 1:74, 1959) observed that when standardized mortality ratios for bronchitis and cancer in the towns of England and Wales were related to the average amounts of undissolved deposit and smoke from the air, highly significant statistical correlations were found with both types of pollution, after eliminating the effects of population density on the correlations. Data were obtained from 58 towns in the industrial areas of Lancashire and Yorkshire. Air pollution was measured by the "deposit index," or monthly average number of grams of undissolved matter deposited per 100 sq. m. of surface, and the "smoke index," which was measured by drawing a known volume of air continuously through a white filter paper for a given time. The darkness of the stain produced was matched with a standard scale and expressed in milligrams per 100 cu. m. of air. The data were averaged over a period of 10 years. Deaths from bronchitis and cancer of the lung, bronchus, stomach, intestine, rectum, and breast were obtained from the statistical reviews of each area over the last five years.

In all areas examined bronchitis was significantly correlated with atmospheric deposit but not smoke, whereas for lung cancer the reverse was true. In Lancashire lung cancer was strongly correlated with population density and this appeared to confirm the effect of wind-borne smoke on the incidence of the disease. The mortality from cancer of the stomach was related significantly to both deposit and smoke in the urban areas, whereas breast cancer showed no correlation with air pollution. The most likely explanation of this is the exposure of food to dirty air. This view received some support from the fact that in the United States, where the wrapping of food was obligatory long before it was in Britain, death rates from gastric cancer have fallen steadily, whereas in Britain they have not. The correlation of intestinal cancer with atmospheric deposit and smoke was below the conventional level of significance.

Medical Honors.—Included in the list of New Year's Honors are Prof. Arthur P. Thomson, this year's President of the British Medical Association, professor of therapeutics, and dean of the faculty of medicine at the University of Birmingham; Dr. Arthur W. Morrow, physician at the Royal Prince Alfred Hospital in Sydney; and Dr. Milton A. Margai, who has been Premier of Sierra Leone since last summer. A knighthood was also conferred on Prof. A. W. Ewing, director of the department of education of the deaf at the University of Manchester.

Politics in Medicine.—Sir Walter F. Hannay, a Harley Street physician, writing in the *Daily Telegraph* of Dec. 2 deplored the intrusion in the last decade of party politics into the realm of medical science and blamed this intrusion for the present retardation in the advance of medical knowledge in Great Britain. The Imperial Cancer Research Fund, a body supported entirely by voluntary contributions, with no political affiliations, must exist on a meager annual budget of $349,510. This brilliant team of scientific workers has absolute intellectual freedom to pursue its investigations, but is sadly hampered by lack of funds. On the other hand, the government-sponsored Medical Research Council has an annual grant of $61,500,000. The 1955-1956 report of this body covered 270 pages of which 210 were devoted to listing the names of the distinguished scientific personnel and only 56 to the work done during the year. The reported findings of the Council made very indifferent reading, and the taxpayer must speculate on the advantages of so costly an association of research workers. This was cited as one more indication of the paralyzing effect of the politician's encroachment into medical science.

Infant Deaths a Mystery.—Mothers have been blamed unjustly or have erroneously thought themselves at fault when apparently healthy children have been found dead in cots. An expert committee, investigating sudden deaths in infancy, has found them innocent of negligence. A member of the committee, Dr. D. M. T. Gairdner, consultant pediatrician, Addenbrooke's Hospital, Cambridge, speaking at a British Medical Association meeting in Southampton, said no evidence that mechanical asphyxiation played an appreciable part in these deaths was found. This is of great comfort to the mothers. Since the cause of these deaths is still unknown, no suggestions as to their prevention can be given. The inquiry lasted over four years; the sudden deaths of 81 children (53 boys and 28 girls) aged 2 weeks to 2 years, or 23% of all deaths in this age group in the areas studied, were investigated.

If this sample was typical, it meant that 1,600 such deaths occurred in England and Wales yearly. These deaths were rare in infants under 1 month and reached a peak in those of 4 months of age; 58 occurred in the six-month periods between November and April. Only seven babies were found lying face down. Mothers at first said that all the children were perfectly well, but inquiry showed that 11 had been seen by a doctor in the three days preceding death and 54 had had trivial symptoms. Autopsies held after 92 such deaths established the cause in only 23. Both breast-fed and bottle-fed babies were involved. The seasonal incidence supported the theory that infection played some part. Dr. Gairdner concluded that mothers should still be advised not to give babies soft pillows because occasionally babies do bury their heads in the bedding.

The Mental Health Bill.—The government's Mental Health Bill is discussed in an annotation in the *British Medical Journal* of Jan. 10. The Bill appeared about 18 months after the report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency and embodied nearly all the important changes recommended by the royal commission and by the British Medical Association's Psychological Medicine Group Committee. As a result of the detailed examination the bill will receive in Parliament no doubt many minor changes will be made in it, but as it stands it represents a notable administrative advance in the care of the mentally ill. Mental health review tribunals are to be set up in the areas of regional hospital boards to consider applications from patients and relatives for their release from hospital. The single term "mental disorder" is to cover all forms of mental illness or disability, and arrangements can be made for any kind of hospital to receive any type of mental patient, whether on an informal basis or under detention. The bill will remove all the formalities which under the present law must be observed before even a voluntary patient can enter a mental hospital, but, in their own interests or for the protection of others, some mentally disordered patients, as in the past, will be compulsorily admitted to hospital and detained therein.

The four groups of mentally disordered patients who may require compulsory detention are the mentally ill, subnormal, severely subnormal, and psychopathic. The terms "mental defective," "idiot," "imbecile," and "moral defective" will no longer be used. Severe subnormality means a state of arrested mental development which renders the patient incapable of living an independent life. Subnormality means a state of arrested mental development which requires or is responsive to medical treatment. Psychopathic disorder means a persistent disorder of personality which results in abnormally aggressive or seriously irresponsible conduct on the part of the patient and requires or is responsive to medical treatment. Patients may be compulsorily admitted to hospital for observation or treatment. In both cases the application will have to be supported by two medical recommendations, one of these by a psychiatrist.

Whether or not the changes brought about by the bill will be notably and quickly advantageous to patients will depend on the attitude of the public to mental illness. The social adaptation of patients discharged from mental hospitals is often precarious. They and their families can receive much-needed support from the aftercare services provided by the hospital and local authorities, but without education of the general public the way may still be hard for those who are trying to overcome a serious disability.

Opposition to "No Strike" Report.—The British Medical Association Council claims that physicians may, under great provocation, be justified in a mass withdrawal from the National Health Service (NHS). This is often referred to in the lay press as going on strike. This is a misrepresentation of what might, in rare circumstances, happen, because physicians would continue to see patients. Sir Frank Newsam, formerly Permanent Undersecretary of State at the Home Office, was commissioned by the General Medical Services Committee, which is representative of the general practitioners who work in the NHS, to investigate the problems and frustrations of the 22,000 family physicians within the NHS and to suggest other ways in which a health service might be organized. The committee wanted an independent inquiry by someone of some eminence. It forwarded Sir Frank's report to the Council of the BMA and the *British Medical Journal* published it with a statement by the Council in the *British Medical Journal* of Jan. 17. The Council strongly criticized the report, asserting that Sir Frank had completely balked the issue he was instructed to grapple with. Although he failed to suggest any alternative schemes his report is not without value. Its value lies in the warning given to the profession that a "strike" would result in a fully salaried NHS. The Council is at this stage refraining from detailed comment, limiting itself to admitting the value of negotiation and the belief that the medical profession, faced with a serious challenge to its principles and traditions, might be compelled to contemplate withdrawal from the NHS.

Sympathectomy for Hypertension.—Newcombe and co-workers of Leeds (*British Medical Journal*, Jan. 17, 1959) reported a series of 212 patients who underwent sympathectomy for hypertension 4 to 10 years earlier. The operative mortality was 4%. The survival rate of 76% for five or more years agrees with other published records of patients treated by sympathectomy and is in favorable contrast to any published account of a series of patients treated conservatively. A sustained reduction of diastolic pressure of more than 20 mm. Hg occurred in 27%. Retinal improvement occurred in 49% of those with severe changes, and when there was no improvement in advanced retinal degeneration death was not long delayed. Symptomatic relief after sympathectomy was the rule. Reduction of blood pressure, if only for a few months, may prevent malignant hypertension. Sympathectomy in hypertension gives many patients an increased expectation of a full and active life.

Menstruation and Acute Psychiatric Illness.—Investigating the time of hospitalization of 276 women with psychiatric disease Dalton (*Brit. M. J.* 1:148, 1959) found that 46% of admissions occurred during or just before menstruation and that 53% of attempted suicides took place during menstruation; successful suicides were more common during the luteal phase. Of patients with depression and of those with schizophrenia 47% were hospitalized during or just before menstruation. The significance of these figures lies in their prognostic value. Psychiatric patients who first seek advice in the premenstruum may be expected to get worse up to the third or fourth day of the menstrual cycle. Premenstrual tension can be successfully treated whether it occurs alone or in association with psychiatric illnesses and regardless of whether the hormonal changes of menstruation cause or precipitate the onset of an acute psychiatric episode. The influence of menstruation on psychiatric admissions was evenly distributed among single, married, and widowed women; among the nulliparous and multiparous; and among those admitted for first and recurrent attacks. There was, however, a marked difference in age. The disturbing influence of menstruation was greatest among those under 25 years of age. Depressive and suicidal patients were evenly distributed among all ages, while schizophrenia was commonest in the youngest age groups. The remaining patients suffered from a wide variety of psychiatric conditions including psychoses, alcoholism, psychopathic disorders, and neurosyphilis. The dates of their admissions were evenly distributed throughout the menstrual cycle.

Bulletin on Rheumatism.—Family doctors throughout Britain now receive a quarterly report on the latest advances in the treatment of rheumatic diseases issued by the Empire Rheumatism Council. The first of these reports was an introductory document in which Dr. W. S. C. Copeman, chairman of the Council, stated that chronic gout has become increasingly common in the last few years.

Spontaneous Improvement in Psychoneuroses.—In assessing the value of any form of therapy it is important to know the degree of spontaneous recovery to be expected from the untreated patient. Wallace and Whyte (*Brit. M. J.* 1:144, 1959) studied the natural history of untreated psychoneuroses in 49 psychoneurotic patients who would normally have had treatment but for various reasons did not. The patients were classified as recovered, improved, or not improved after follow-up periods of three to seven years. Some improvement was noted in 32 (65.3%). Any recovery that occurred spontaneously did so by the third year. The better-integrated patients showed a higher recovery rate and a greater capacity for adjusting to adverse and difficult circumstances. Factors associated with improvement were a helpful marriage partner, adequate housing, good personality, success in work, general adequacy in life situations, and participation in group activities. This high spontaneous recovery and improvement rate must be borne in mind when assessing the value of any new form of treatment, whether by drugs, psychotherapy, or physical methods.

Zollinger-Ellison Syndrome.—Further cases of the recently described Zollinger-Ellison syndrome were reported by Summerskill and Pender (*Lancet* 1:120, 123, 1959). This syndrome is characterized by *gastric hypersecretion, fulminating atypical peptic ulceration*, and pancreatic islet cell hyperplasia. Diagnosis is usually made retrospectively after gastric operation or at autopsy. Summerskill reported a case diagnosed before operation. The patient had jejunal ulcers and secreted over 500 ml. of gastric fluid hourly with practically no response to histamine stimulation. Acid-pepsin activity was present in the jejunum. Diarrhea and steatorrhea were prominent clinical features. Fat digestion in the jejunum was depressed by the presence of acid, and this caused the steatorrhea and diarrhea. Pender's patient had an islet cell tumor of the pancreas. The patient's daughter also had a benign islet cell adenoma. The patient had had repeated but unsuccessful operations for recurrent peptic ulcers. Eventually treatment by total gastrectomy and removal of the benign islet cell tumor resulted in improvement.

Poliomyelitis Vaccine.—An electron microscope will speed the search for a poliomyelitis vaccine produced without the use of monkeys. This and an analytic centrifuge will be bought by the National Fund for Poliomyelitis Research. Britain and the United States together use nearly 30,000 monkeys a month for producing and testing vaccine, and other countries are entering the production field. Research workers feel that in time the demand for monkeys may outstrip the supply. Each monkey yields about 700 doses of vaccine and costs the manufacturer about $42. There have been difficulties about their export from India, because in some areas monkeys are regarded as sacred animals.

Curtains and Hospital Contamination.—Hughes (*Lancet* 1:152, 1959) studied a 14-bed general surgical ward in an attempt to discover possible causes of wound sepsis. Weekly tests were made from samples of the curtains, which were cotton and of the pull-round type. Staphylococcus pyogenes was isolated from 54% of 250 samples. On one occasion clean curtains, which had been through a high-pressure steam sterilizer, were put up around the bed of a patient who had a staphylococcic wound infection of known bacteriophage type. In less than 24 hours the same bacteriophage type of staphylococci was isolated in large numbers from the curtains.

Health of School Children.—In his report on the School Health Service (The Health of the School Child, Her Majesty's Stationery Office, 1959) Sir John Charles, Chief Medical Officer of the Ministry of Education, stated that one of the main health problems in children is overnutrition and not malnutrition. He blamed too many candies, chocolates, ices, and cookies and too much carbohydrate in the diet. On the credit side, boys and girls are taller, heavier, better clad and shod, and cleaner than they were 50 years ago. They reach physical maturity earlier and may expect to live 20 years longer. Tuberculosis, rickets, and rheumatism in children have been virtually eliminated. Most cases of crippling and deformity are now congenital. More children die from accidents than from disease. Traffic accidents are the cause of half the deaths in children, and many of these occur when children are going home from school. Children should be told about the risk of lung cancer from smoking cigarettes as many school children smoke. An inquiry among 300 boys and girls in a high school on the Isle of Wight revealed that 30% of the boys and 15% of the girls were regular smokers. Increased consumption of candies and chocolate was blamed for the increase in dental decay in children. The school medical service is devoting more attention to emotionally disturbed and delinquent children. The number of children appearing in the juvenile courts has increased in 25 years from 13,000 to 38,000 annually. The school medical service now covers 6,500,000 children in 30,000 schools and more than 2,000,000 have an annual medical examination.

New Deal for Midwives.—The Minister of Health proposed a new deal for midwives to meet the serious shortage in the hospital and private midwife service. Among the recommendations made was the employment by the maternity services of more auxiliary nursing and domestic staff to enable midwives and midwives in training to get on with their professional work. It was also suggested that midwives should have responsibility for individual patients throughout the patients' stay in hospital. New maternity hospitals should be planned with this end in view. Unnecessary rules and restrictions should not be applied to pupil midwives, particularly when off duty, and they should have better opportunities for training than at present. Provision should be made for training women who have no nursing qualifications as midwives. The satisfaction the midwife gets from her work could be increased by inculcating a more appropriate mental attitude in patients and their relatives toward her profession.

Radioactive Fall-out and Leukemia.—An investigation is being carried out by the Lancashire Health Committee into the cause of the reputed increase in deaths from leukemia and aplastic anemia in the district and its possible association with the radioactive fall-out that occurred at Windscale, Cumberland, in October, 1957. A plutonium plant became overheated and quantities of fission products, including radioactive iodine (I^{131}) contaminated the surrounding countryside. It is reported that several young people in the area have died from aplastic anemia. The local health officer is conducting the investigation. All county health officials have been asked to report cases of leukemia and aplastic anemia. Medical Research Council experts think it unlikely that the Windscale accident is linked with deaths from leukemia or aplastic anemia. The major component of the fall-out was I^{131}, which has never been linked with leukemia or aplastic anemia. Neoplastic changes after irradiation do not occur until many years after exposure. As leukemia is rare fluctuations may occur from time to time in any area.

CORRESPONDENCE

ANTIBIOTIC LOZENGES

To the Editor:—In the past few years I have seen a fairly large number of patients who have complained of severe sore throat after using antibiotic lozenges. This was due to infection caused by Candida albicans. In all of these patients the soft palate and pharynx were extremely red. In some there were small white patches indicating the presence of colonies of C. albicans. The pain is more severe in this condition than in that associated with any of the inflammatory diseases of the mouth and throat, including severe streptococcic infections. There have been cases of prolonged illness and even death from this cause. For some time I have questioned the moral and legal right of the manufacturer to market a product so injurious to health and at times to life itself. About 25 different antibiotic lozenges are offered for sale. Some contain more antibiotics than others. At least two are advertised extensively on radio and television.

Following is a list of antibiotic lozenges which are sold on prescription or over the counter in the average pharmacy.

- Single Antibiotic Troches
  - Achromycin pharyngets (Lederle)
  - Achromycin troches (Lederle)
  - Aureomycin pharyngets (Lederle)
  - Terramycin troches (Pfizer)
  - Bacipharyn (Reed & Carnrick)
  - Baci-Troche (Upjohn)
  - Teeds lozenges (Warren-Teed)
  - Pemzoles lozenges (Pitman-Moore)
  - Lozilles (White)
  - Tyrosan lozenges (Recsei)
- Combined Antibiotic Troches
  - Sul-Pondets (Wyeth)
  - Bacillets (Abbott)
  - Pondets, Penicillin-Bacitracin (Wyeth)
  - Candettes (Pfizer)
  - Du-Biotic troches (White)
  - Orobiotic (White)
  - Spectrocin (Squibb)
  - Tracinets troches (Merck, Sharpe, & Dohme)
  - Wybiotic troches (Wyeth)
  - Pentazets troches (Merck, Sharpe, & Dohme)
  - Hydrozets (Merck, Sharpe, & Dohme)
  - Tetrazets (Merck, Sharpe, & Dohme)
  - Isodettes (Isodine)
- *Penicillin G Crystalline* Troches
  - Troches with 5,000; 10,000; 20,000; or 25,000 units each (various manufacturers)
  - Troches with 5,000 units of crystalline penicillin G with benzocaine
  - Troches with 5,000 units of procaine penicillin G

Each of the antibiotic lozenges, regardless of the number used, can permit a Candida infection of the soft palate and pharynx to gain a foothold. If we multiply the several hundred cases which I have seen by the number of family physicians and specialists who have also seen similar cases, the aggregate number and the number of work days lost would be staggering.

The purpose of this letter is to ask what can be done toward a discontinuance of the sale of all antibiotic lozenges. The fact that some physicians prescribe these lozenges cannot be construed as an argument in favor of their use. Many doctors are not aware of the danger involved in using antibiotic lozenges. Unfortunately, few articles have been written by those who have encountered patients with Candida infection of the mouth and throat. Frequently the physician who prescribes the lozenges does not see the patient at the time the severe sore throat develops. Action taken by members of the medical profession could do much to stop this health menace.

CHLORPROMAZINE JAUNDICE

To the Editor:—I wrote a report on chlorpromazine jaundice, more than two years ago, based on 17 cases (Hollister, *Am. J. Med.* 23:870, 1957); since that time I have seen only one other case. This declining prevalence of jaundice has also been noted by another observer (Pollack, *Am. J. Psychiat.* 113:1115, 1957). To provide further information, questionnaires were sent to 67 psychiatrists and mental hospitals using or investigating tranquilizing drugs; 45 replies were received, providing the following data.

In the year preceding the inquiry, 25 of the respondents had encountered at least one case of chlorpromazine jaundice, while 20 had encountered none. Eighty-seven cases of jaundice were reported by these 25 sources, the largest single series being 13 cases. Data were sometimes incomplete in regard to the number of patients treated for the first time with chlorpromazine during the same period. Available data showed that 70 cases of chlorpromazine jaundice had occurred in about 15,000 patients treated, a prevalence of about 0.5%. Of those respondents expressing an opinion, 20 thought that the recent prevalence of chlorpromazine jaundice was lower than that of their previous experience, and 14 thought that it was similar. None thought that it was higher. The customary practice of most clinicians was to discontinue the drug therapy or switch to another if jaundice occurred; only three continued chlorpromazine therapy throughout the episode of jaundice.

Various reasons were given to explain the lowered prevalence of this complication by those who thought such was the case, the most frequently mentioned reason being that current dosage tended to be lower and better controlled because of prior experience. This reason is contrary to the experience of many investigators that the dosage of drug *bears little relationship to the production of jaundice.* The second most common reason cited was that impurities originally present in the drug had now been removed due to more reliable methods of manufacture. The manufacturer of the compound disclaims this possibility, pointing out that chlorpromazine is a synthetic compound. Also, other phenothiazine derivatives produce similar jaundice, and it is unlikely that all would have the same contaminant. Another idea was that a period of high prevalence of infectious hepatitis could have coincided with the early use of the drug, the latter making patients more susceptible to this illness. Also mentioned were the elimination of patients with known liver disease, the use of alkaline phosphatase determinations as screening during the early phase of treatment, and the fact that many patients may have been previously treated without the knowledge of the physician and thereby "desensitized" to the drug.

Jaundice was reported as a complication of three other phenothiazine derivatives: promazine, mepazine, and prochlorperazine. In the case of the latter drug only one report was received, despite the fact that many of the respondents noted that they were using this drug increasingly. The majority opinion is that chlorpromazine jaundice is a drug allergy. The declining prevalence of this complication with increasing exposure of the population to it is contrary to the usual experience with allergic reactions to drugs. The explanation for this phenomenon is still not clear.

Palo Alto, Calif.

ELI LILLY MEDICAL RESEARCH FELLOWSHIP (SOUTH AFRICA)

To the Editor:—Medical practitioners who are registered in South Africa and who may at present be in the United States should be aware of the fact that applications may now be submitted for the 1959 award of the Eli Lilly Medical Research Fellowship. The fellowship is for the purpose of research and is not for postgraduate clinical study. The net value of the fellowship is $300 a month for 12 months, plus return traveling expenses to the point of study in the United States of America. Further details can be obtained from the undersigned. The closing date for applications is June 30, 1959.

H. A. Shapiro
P. O. Box 1010
Johannesburg, South Africa.

MUSEUM OF MEDICAL SCIENCE

To the Editor:—We in the Wellcome Museum of Medical Science have read with great interest the letter by Dr. Frederick Stenn in The Journal (169:67-68 [Jan. 3] 1959). To us has been entrusted the task of maintaining the museum of medical science as a teaching institution designed primarily for postgraduate medical men but suitable, also, for undergraduates, nurses, teachers of biology, and their senior students.

The various aspects of medicine now dealt with in this museum are divided on an etiological basis. Thus, we have eight major heads, namely, protozoal diseases, diseases due to bacteria, diseases resulting from viruses, diseases of rickettsial origin, helminthic diseases, fungus diseases, spirochetal diseases, nutrition and malnutrition, and a small section dealing with venomous snakes and arthropods. The method used to describe these conditions is an elaboration of that devised by the original director of this museum, the late Dr. Daukes. The written matter is presented in a synoptic fashion, illustrated by charts, diagrams, pictures, roentgenograms, gross pathological specimens, and photomicrographs illustrating the histological, pathological, entomologic, and parasitological aspects of the conditions described.

Recently the section of the museum dealing with schistosomiasis was shown at a meeting of the South African Medical Association, in Durban, and the section on trypanosomiasis was on display at the Sixth International Congress on Malaria and Tropical Diseases, in Lisbon. The administrative problems in arranging loans are formidable, a matter well appreciated by all museum curators; but on occasion we have been able to supply some material for use by individuals and institutions who have applied to us for assistance.

We do not fully agree with some of the methods of audiovisual instruction proposed by Dr. Stenn. Some of them go against the ancient axiom that clinical medicine can be effectively learned at the bedside and at the bedside only. We have, however, been much interested to see that the concept of using a museum as a main center for medical teaching has found expression in a letter in The Journal. Changes in medical education evolve but slowly. The example and the potentialities of the system followed in the Wellcome Museum of Medical Science have been increasingly appreciated in the United Kingdom during the 45 years of the museum's existence. We shall be greatly interested to see what developments, if any, may take place in the United States as a result of Dr. Stenn's spirited appeal.

THE LEISURE CORNER

PART-TIME FARMING

Growing things for profit is not quite the same as growing them for fun, but trying to get a profit out of the soil can provide a great deal of pleasure as a part-time hobby for a physician with an independent income. In part-time farming physicians can get away from the complex problems associated with medical practice and find relaxation in what amounts to a completely different occupation. It is possible to trace concrete accomplishments in farming and to realize a sense of progress and gratification.

A part-time farmer owns his own farm and generally lives on it for at least a part of the year. The farm usually starts off being a place for week-ends and summer vacations. Part-time farming is a quite different and more ambitious procedure than tending a garden about one's home. Actually, many of the problems facing the part-time farmer are similar to those confronting the full-time farmer, with one major difference: the part-time farmer does not depend on his hobby to make financial ends meet.

If you have never worked on a farm it is likely that you have some idyllic notions about the kind of life it affords. Returns are not always up to expectations. When you plan to buy a farm make certain it is in a reasonably accessible location. Investigate all phases of farming with the same perspicacity you would apply to evaluating a medical problem. Your first concern should be equipment. Is your back strong enough to do your own plowing, or should you hire someone else to do it? Do you need one or more horses? What equipment should be purchased and what rented? Do you intend to raise fruit? Do you intend to raise chickens and rabbits? These are some of the questions the part-time farmer must answer. Livestock cannot be neglected; someone must always be on hand to keep a close watch. When arrangements are made it is essential to keep an eye on cost.

If you plan to make part-time farming the profitable hobby it can be, it will be necessary, among other things, to investigate the market for cash crops and determine what crops are adapted to your locale and soil. In this connection, the best procedure to follow is to obtain the advice of neighboring farmers, county agricultural agents, and the state agricultural college. You will probably be told that it is better to raise a small quantity of several crops rather than a plentiful amount of a single one. Then there is always the question of feed; whether to buy it or raise it often depends on how much money is available for this purpose.

If you have read this far and are still intrigued by the thought of part-time farming, you might turn to an excellent book called "Practical Animal Husbandry," by Jack Widmer (Charles Scribner's Sons, 1949). He asserts that anyone interested in farming will be surprised at how quickly it is possible to learn to handle farming problems. The author emphasizes the importance of owning a deep freeze unit and supplies some intriguing information about sheep, hogs, rabbits, turkeys, chickens, ducks, geese, squab, guinea fowl, and beef and about meat processing. He speaks of his farm in northern California, where he has fields of hay, grain, and pasture which supply feed for his animals and a cash income from the surplus.

Many forest products, such as fuel wood, saw logs, veneer logs, posts, pulpwoods, crossties, and piling, can bring ready cash. In certain areas it is possible to grow many types of green nuts, berries, and evergreen trees. Turpentine, maple syrup, and cascara bark can find a market, and should you find yourself with an abundant supply of wild shrubs, there is a demand for them from people who have moved to suburban areas. For those who are attracted to raising bees, only a small investment is required, since bees do not require an abundance of attention.

Although most herbs are grown readily, they, too, must be studied beforehand. Many farmers start out with the six best known herbs, sweet basil, chervil, sweet marjoram, thyme, rosemary, and tarragon; then with more experience one can add the so-called mixers, chive, parsley, and summer savory. When you have become a proficient farmer and have developed a keen taste, similar to that of the gourmet, you can add to your stock anise, caraway, celery, fennel, garlic, and mint. Herbs are the ornamental touches you give to your farm. They can be grown in flower beds, rock gardens, or in special herb gardens situated right outside of the kitchen.

Fur farming is a long-term project and there is no easy route to profit. This specialized type of farming holds a great deal of attraction for physicians, however, especially in the creation of various mutations among fur-bearing animals. Cross-breeding, once begun as a scientific experiment, has grown to be one of the most profitable aspects of fur production. The quickest way to become familiar with the specialized body of knowledge is to visit successful fur farms and talk to the owners. Some states require licenses; therefore, before embarking on the raising of mink or chinchilla, it is best to write to the Department of Agriculture for a list of fur farm associations. You will then be able to learn about breeders, prices, and places to buy stock. Since the fur business is also a fashion business it is advisable to make a study of current fashion trends. At present mink is a most popular item, but one never knows when the fashion cycle will change and fickle fashion turn to another flirting pelt. Other fur-bearing animals are so plentiful, namely beaver, skunk, and muskrat, that there is little point at present in raising these animals for commercial purposes. This would be at best a rather costly bit of amusement.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Serum Cholesterol in an Office Practice. A. I. Josey. J. South Carolina M. A. 54:439-443 (Dec.) 1958 [Florence].

The author made 216 determinations of the serum cholesterol level in 59 patients seen in his private office. There were 57 men and 2 women, all in middle or later period of life. The Bloor method employing the Lietz photrometer was used, and all blood samples were obtained in the morning after a fasting period of at least 12 hours. Twenty-four of the 59 patients did not present any clinical evidence of atherosclerosis. Of these 24 patients, 11 had one or more determinations in which the serum cholesterol level was 250 mg. per 100 cc. or below and 13 had one or more determinations above 250 mg. The remaining 35 patients had definite evidence of one or more of the complications of atherosclerosis. Of these 35 patients, 17 had one or more cholesterol determinations of 250 mg. and above, and 18 had determinations below 250 mg. Eight patients with myocardial infarction fell into the group with serum cholesterol levels above 250 mg. per 100 cc., and 9 cases of infarction occurred in the group of patients with serum cholesterol levels below 250 mg.

Sixteen patients with clinical manifestations of atherosclerosis, who were chosen for their motivation and ability to cooperate, were put on maintenance therapy with a diet low in saturated and hydrogenated fats in conjunction with corn oil, and a preparation of safflower oil containing 80% linoleic acid, in doses of 15 to 30 cc. daily, was regularly prescribed for from 5 to 12 months. The total caloric intake was adjusted in each patient to obtain or maintain an optional weight. These 16 patients had serum cholesterol determinations at intervals of one month or more for a total of 5 to 10 determinations. Twelve of the 16 patients had no significant changes in serum cholesterol levels; 4 patients showed a tendency to a lowered level, but this was not consistent or persistent. The diet, therefore, failed to reduce consistently the levels of serum cholesterol in this group of 16 patients.

The level of serum cholesterol above or below 250 mg. per 100 cc. in single or serial determinations did not reflect the presence or absence of clinical complications of atherosclerosis in the 59 patients. The level of serum cholesterol found at various intervals was quite variable and erratic in presumably normal individuals and in atherosclerotic men, and because of this variability the serum cholesterol level does not appear to be of any value for the prognosis of the development of complications of atherosclerosis.

On the Bradycardic Effect of Reserpine. T. Albano and R. Motta. Minerva med. 49:3904-3909 (Oct. 17) 1958 (In Italian) [Turin, Italy].

The bradycardic effect of reserpine was studied in 38 patients with sinus tachycardia; this condition was due to mitral valvular disease in 8 patients, essential hypertension in 10, chronic cor pulmonale in 4, hyperthyroidism in 5, neurodystonia in 6, and atrial fibrillation in 5. Each patient received an initial dose of 1 mg. of reserpine per day, given intravenously for 4 to 6 days, and a maintenance dose of 0.25 mg. per day, which was continued for as long as the clinical course required it. A return to normal values was obtained within 3 to 5 days in the heart frequency of the 8 patients with mitral valvular disease; subjective symptoms disappeared. The heart action of a 21-year-old woman, who presented tachycardia both at rest and on exertion, dropped within 3 days from 144 to 70 beats per minute, and her general condition improved. Reserpine alone was sufficient to check the marked tachyarrhythmia of one patient with atrial fibrillation; this patient had derived little benefit from previous treatment with digitalis or quinidine. Reserpine was likewise beneficial in 2 of the remaining 4 patients with atrial fibrillation. The pulse rate dropped markedly in the 10 patients with essential hypertension. Good results were obtained in the 4 patients with cor pulmonale: the frequency of the heart became normal, dyspnea disappeared, and cyanosis became more attenuated. Good results were also obtained in the 5 patients with hyperthyroidism and in the 6 with neurodystonia. Side-effects occurred in 2 patients. In one patient with total arrhythmia the treatment had to be suspended because of marked subjective disturbances, which could not be checked by re-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

ducing the daily dose of reserpine; the other patient suffered marked asthenia, which was checked by changing the dose of 1 mg. given intravenously to 0.5 mg. given by mouth.

Familial Occurrence of Congenital Heart Disease: Report of Three Families and Review of the Literature. R. A. Carleton, W. H. Abelmann and E. W. Hancock. New England J. Med. 259:1237-1245 (Dec. 25) 1958 [Boston].

The authors report on 3 families who were studied at the heart station of the Boston City Hospital; among the members of these families 9 with congenital heart disease were found. The first family was composed of the parents and 9 children, and 3 of the latter had congenital heart disease; the second family was composed of the parents and 5 children, and 2 of the latter had congenital heart disease; the third family was composed of 72 members, and 3 sisters and the daughter of one of these sisters had congenital heart disease. One patient in the first family, 2 persons in the second family, and the 3 sisters in the third family had a defect of the atrial septum. Six of the 9 patients with congenital heart disease underwent cardiac catherization; it was this procedure which revealed a defect of the atrial septum in the 3 sisters in the third family, thus permitting the first report of 3 cases with a defect of this type in one family diagnosed by other than clinical means. An additional 141 cases of multiple familial congenital heart disease were collected from the literature, including 4 families with more than one member with a defect of the atrial septum. Environmental gestational factors may sporadically be causative, but the findings in the patients reported on appear to conform best with a single, recessive, autosomal mode of genetic transmission.

Staphylococcal Parotitis. R. G. Petersdorf, B. R. Forsyth and D. Bernanke. New England J. Med. 259:1250-1254 (Dec. 25) 1958 [Boston].

The authors report on 3 men and 4 women, between the ages of 50 and 85 years, with a virulent and hitherto rare form of hospital-acquired staphylococcic parotitis. With one exception, the patients were advanced in age and had severe, debilitating, chronic diseases. In 3 patients, in whom the parotitis was intimately related to a major surgical procedure (cecostomy, suprapubic prostatectomy, or cholecystectomy), the infection within the salivary gland appeared within a week of the operation. In 6 patients the parotitis occurred in the hospital, and in 1 it occurred 2 weeks after discharge from the hospital. Dehydration seemed to be an important predisposing factor and was present in 5 patients. One patient, however, had massive edema. The presence of a tracheostomy tube may have played a part in 2 patients. The clinical picture was characterized by the sudden onset of a firm, warm, erythematous, indurated swelling at the angle of the jaw and over the cheek, associated with fever, local pain, and tenderness and with a high white blood cell count (mean count, 33,000 per cubic millimeter).

Staphylococci were isolated in all patients from the pus released from the orifice of Stensen's duct and were cultured in 6 patients. The organisms were invariably resistant to penicillin, streptomycin, and the tetracyclines; some were inhibited by erythromycin and chloramphenicol; and all were sensitive to neomycin, bacitracin, nitrofurantoin, and novobiocin. Phage typing indicated the presence of an unusually resistant strain (type 80-81) in 3 patients. Five patients survived, and 2 died. Treatment was most effective when antibiotics to which the organisms were sensitive were employed. There was no relationship between the response to treatment and the nature or severity of associated disease. Dehydration and routine prophylactic use of antibiotics should be avoided, since they appear to be the most important predisposing factors in the development of staphylococcic parotitis.

Erythema Infectiosum (Megalerythema): Epidemic in West Germany. H. T. Schreus. Deutsche med. Wchnschr. 83:2165-2167 (Dec. 5) 1958 (In German) [Stuttgart, Germany].

A large number of patients with erythema infectiosum are being seen by general practitioners and industrial physicians and in clinics in West Germany. The symptoms and the course of the disease in the individual patient show that the disease is not new. Epidemics of this skin eruption, which has been designated as erythema infectiosum, epidemic megalerythema, Ringelröteln (ring rubella), large-spotted disease, or simply fifth disease, were reported several times before in Germany. The present epidemic seems to be much more extensive than the previous ones, although exact figures of the incidence of erythema infectiosum cannot be given, since it is not a reportable disease. Another unusual aspect of this epidemic is that the disease is more frequent in women than in children. As regards the nomenclature, the author feels that the term "ring rubella" is inadvisable, because erythema infectiosum has no relation to rubella (German measles).

The disease usually begins in the face or as an enanthem in the mouth, that is, the fauces and the mucosa of the soft palate are somewhat red and occasionally may even show petechial hemorrhages. Spotty outlines on the buccal mucosa and slight redness of the tongue are also observed occasionally. At about the same time, spotty or confluent redness is observed on the cheeks. There may be complaints about itching, moderate headaches, lassitude, and mild sore throat. Increase in temperature is slight. Extension of the eruption from the cheeks to the neck, and from there to the upper arms and wrists, sometimes sparing the elbow region, is rather rapid, as is also the extension to the lower extremities. During the early stage, the eruption resembles that of measles, except that it is somewhat more papular; it is intensely red. The small papular form of eruption usually does not persist until disappearance, but may be followed by large-surfaced, confluent areas of erythema, with relatively sharp but irregular outlines (map-like). The center may become lividly blue, and then dirty brown, whereas the rim remains red, so that at this stage the term "Ringelröteln" may seem justified. The process is not limited to the extremities, for as during the present epidemic the entire body may be involved, even to the palms of the hands and the soles of the feet.

The duration of the exanthem varies; sometimes it is subsiding on the face, while it is still in "full bloom" on the extremities. The etiology has not been completely clarified, but a virus origin is widely accepted. The prognosis is favorable, and no damaging effects on the fetus have been observed when erythema infectiosum occurred in pregnant women. The simultaneous appearance of cases in families and industries is more evident than are successive attacks resulting from contacts. This fact and the favorable prognosis indicate that isolation of patients and closing of schools and factories are unnecessary. As regards treatment, the author recommends only symptomatic therapy, since active therapy might interfere with the immunization processes that are characteristic of the exanthematic diseases.

Histoplasmosis in East Africa. P. E. C. Manson-Bahr. East African M. J. 35:625-629 (Nov.) 1958 [Nairobi].

Histoplasma capsulatum, the organism causing histoplasmosis, is found in 2 forms: (1) the mold-like saprophytic form and (2) the yeast-like parasitic phase. H. dubosii, which is the African form of the Histoplasma organism, is larger in size than H. capsulatum. Infection is caused by the mold phase, which lives in the body as the yeast phase and invades the reticuloendothelial system. Infection is from the saprophytic form in the soil, which has been contaminated by the droppings of birds and bats. The disease does not spread from man to man, but infection takes place from the inhalation or ingestion of dust. Thus, in the epidemiology of this disease enclosed spaces, such as caves, pigeon lofts, and chicken houses, where there is contaminated soil, are of great importance. There are 3 main forms of the disease: the localized form, the generalized disseminated form, and benign pulmonary histoplasmosis. After discussing these 3 forms on the basis of literature reports, the author comments on the incidence of sensitivity to histoplasmin in various regions. Surveys in Africa have shown that sensitivity rates vary from 0 to 17.8% in different parts of the continent, miners from the gold mines of Nyanza province in East Africa showing the highest incidence among miners in Africa. An interesting form of benign pulmonary histoplasmosis in South Africa is known as "cave disease." It was found in members of a speleological society, who had been exploring certain caves in the Transvaal.

Recently a patient with cave disease, the first to be described, from East Africa, came under the author's care. He contracted the disease during an exploration of the Amboni caves near Tanga in Tanganyika. There were many bats, and the floor was covered with guano. The man examined the bat guano closely for insects and ticks. Fourteen days later he started to run a fever up to 104 F (40 C) with rigors and sweats. After the first week the fever began to decline, but was still up to 101 F (38.3 C) when he was admitted to hospital about 3 weeks after the onset of symptoms. Roentgenoscopy of the lungs revealed ill-defined coarse mottlings scattered throughout both lungs. A Friedländer pneumonia or tuberculosis was considered. Later a histoplasmin skin test produced a strongly positive skin reaction to a 1/1,000 dilution. Treatment with penicillin and Chloromycetin had no effect, neither did nystatin and sulfonamides or hydroxystilbamidine and large doses of potassium iodide. The lung mottlings gradually cleared and the cough subsided, but there were still some x-ray changes in the lungs 5 months after infection.

The diagnosis of benign pulmonary histoplasmosis rests upon the history of exposure to bat guano, persistent pulmonary mottlings unlike any other condition, a strongly positive histoplasmin skin reaction, and a positive complement-fixation test. It is unusual to isolate H. capsulatum from this type of patient. Disseminated histoplasmosis should be thought of as a possibility in patients with prolonged pyrexia, with hepatosplenomegaly when leishmaniasis and brucellosis cannot be incriminated. Benign pulmonary histoplasmosis should be considered in diffuse coarse miliary mottlings of the lungs, especially where the Mantoux reaction is negative.

Urinary Tract Infection in Paralytic Poliomyelitis. H. D. Riley Jr. and V. Knight. Medicine 37:281-297 (Dec.) 1958 [Baltimore].

As the result of improved treatment of respiratory failure, there is an increasing number of survivors of paralytic poliomyelitis, in whom factors inherent in severe poliomyelitis and its treatment, including immobilization, urolithiasis, catheterization of the urinary bladder, and possibly antibacterial treatment, may lead to urinary tract infection. The authors studied this form of urinary infection over a 21-month period at the poliomyelitis respiratory center at Vanderbilt University Hospital, Nashville, Tenn. There were 50 patients, of whom 15 entered at the time of onset of acute poliomyelitis, while 33 were admitted 30 days or longer after onset of their disease. Two patients with acute transverse myelitis of uncertain origin have been included in this study. Thirty-five patients were over 15 years of age; 15 were younger. Twenty-six patients were males, and 24 were females. All patients were observed for periods ranging from 2 to 16 months. All but 3 patients experienced persistent respiratory insufficiency, necessitating mechanical aids to respiration. Blood pressure determinations were made at least twice daily on all patients throughout the study. Urine was collected for study weekly, or more often, from all patients regardless of evidence of urinary tract infection. Catheterization was dispensed with, and the urine specimen was collected from the midportion of the uninterrupted stream in a sterile container. The first morning specimen was not used, to avoid the overnight growth of bacteria in bladder urine.

Urinary tract infection was demonstrated in 44 of the 50 patients. It can be assumed that renal tissue damage from persistent or recurrent infections will become a factor of increasing importance in the prognosis of these patients. The disease is characterized by its indolence, frequent lack of urinary symptoms, persistence, and steady progression. Bladder catheterization and general immobilization are important influences in the development of urinary tract infection. Treatment is only slightly effective. A presumed result of frequent use of antimicrobial drugs is a high predominance of Bacillus proteus and Aerobacter aerogenes in cultures of urine. Urolithiasis was present in 21 of the 44 patients with urinary tract infection. Twenty per cent of the patients exhibited persistent diastolic hypertension, which appeared to result from some effect of poliomyelitis other than renal damage by infection.

Variations in the Course of Rheumatoid Arthritis. P. E. Brown and J. J. R. Duthie. Ann. Rheumat. Dis. 17:359-364 (Dec.) 1958 [London].

In previous papers of this series the course of a group of patients with rheumatoid arthritis after admission to hospital was described. Changes in functional capacity and disease activity were considered for the group as a whole. The present communication is concerned with the types of course pursued by individual patients and particularly with the question of whether an appreciable number of patients showed a tendency toward permanent recovery or toward permanent disablement. Functional capacity and disease activity were determined on admission to hospital, on discharge, and at 3 subsequent assessments approximately 2 years apart. Four functional grades were distinguished. Patients with fitness for all normal activity were classified as grade 1; those with moderate restriction of function as grade 2; those with marked restriction as grade 3; and those confined to bed or chair as grade 4. Disease activity was assessed as very active, moderately active, or inactive, according to the erythrocyte sedimentation rate, the hemoglobin level, the presence of signs of inflammation in the joints, and the degree of systemic disturbance.

Studies were made on 247 patients. There seemed to be a tendency for patients to remain at approximately the same functional level for fairly long periods after treatment in hospital; 56% of the patients remained in the same functional grade at the 3 assessments after discharge, and 79% remained either in grades 1 or 2 or in grades 3 or 4. As time went on, a small percentage of patients drifted from the more favorable to the disabled groups. There was little evidence that patients in whom the disease ran the most benign course could be regarded as cured. Of those showing no disability throughout the period of observation, half continued to show signs of disease activity. Only 7% of the total number of patients retained full functional capacity and showed no signs of disease activity after discharge from the hospital. A high proportion of those who were severely disabled still showed signs of disease activity. There was no evidence that in any of these patients the disease had "burned itself out." The prognosis was most favorable in patients who had run a progressive course since the onset of symptoms and had been admitted to hospital within one year of onset.

Tophaceous Gout in a 17-Year-Old Male. K. Davison. Postgrad. M. J. 34:651-653 (Dec.) 1958 [London].

Although tophi are present at the onset of gouty arthritis in 2% of patients, the average time between the onset of gout and the appearance of tophi is 15 to 20 years. In most of the published cases of juvenile gout, tophi were absent or did not develop till the patients were much older. The patient described was a youth of 17 years, who 18 months before admission suddenly experienced pain and swelling in the interphalangeal joints of some of his fingers. Within a few days both ankles and the metatarsophalangeal joints of both big toes were also affected. A diagnosis of acute rheumatism was made, and the patient was treated with bed rest and aspirin. The arthritis slowly subsided over a period of 2 months, but a month later both elbows became swollen and painful and remained so for a month. After an interval of 3 months the ankles, big toes, and elbows were all affected simultaneously for a period of 3 months. Six months before admission the patient had an attack of left renal colic with hematuria. Pyelography revealed no abnormality. At about the same time he was seen by an orthopedic surgeon, who diagnosed rheumatoid arthritis. Shortly afterwards the patient noticed small nodules in his right pinna, over the right patella, and both elbows. Intermittent arthritis continued until his admission to hospital.

Examination revealed white pearly nodules in the right pinna, small subcutaneous nodules over the right patella and the right second metacarpophalangeal joint, and large yellowish nodules in both olecranon bursae, the left one having ulcerated through the skin. Effusions were present in knees and elbows, with pain and limitation of movement. The metatarsophalangeal joint of the right big toe was swollen and red. The blood urea content was 44 mg. per 100 cc., and the serum uric acid was 12.2 mg. per 100 cc. Material from the ulcerated tophus was identified as urate. The patient was treated initially with colchicine by mouth with marked symptomatic improvement. Probenecid (Benemid) was then given orally in a dose of 1 Gm. twice daily, together with a high-fluid intake and a low-purine diet. This treatment was continued, and, apart from a transient recurrence of arthritis, the patient remained symptom-free.

Juvenile gout often differs from adult gout in the absence of classical podagra and the frequent occurrence of polyarthritis. This led to diagnostic difficulty in this patient, but at the time of his admission to hospital the presence of multiple gouty tophi, together with the recurrent acute peripheral arthritis, enabled a clinical diagnosis of gout to be made, which was confirmed by the high serum uric acid level. No family history of arthritis was obtained, and the serum uric acid levels of the available relatives were all within normal limits of 4 to 6 mg. per 100 cc.

Assessment of the Relative Importance of the Allergic, Infective and Psychological Factors in Asthma. D. A. Williams, E. Lewis-Faning, L. Rees and others. Acta allergol. 12:376-395 (no. 6) 1958 (In English) [Copenhagen].

The authors report on 487 consecutive patients with asthma, who attended the asthma clinic of St. David's Hospital in Cardiff, Wales, between 1951 and 1954. There were 274 male and 213 female patients; 248 were children, and 239 were adults. Boys predominated among the children, and women among the adults. Analysis of the causes of asthma in these patients revealed that an infective factor was present in 88%, a psychological factor in 70%, and an allergic factor in 64%. All three factors played a part in the precipitation of asthma in 38%; the infective and psychological factors only played a part in 23%, the allergic and infective factors in 15%, and the allergic and psychological factors in 7%. The infective factor was the only factor causing asthma in 11%, the allergy factor was the sole cause in 3.3%, and the psychological factor was the only cause in 1.2%. The dominant precipitating causes of asthma were the allergic factor in 29%, the infective factor in 41%, and the psychological factor in 30%. Analysis of these causes, as found among the different age groups, suggested that in children up to 5 years of age the psychological factor was the most frequent, and in the group over 45 years of age the infective factor was by far the most important precipitating cause. Supportive evidence of the likelihood of these general observations being correct is given.

SURGERY

Congenital Aortic Stenosis: Clinical and Hemodynamic Findings, Surgical Technic, and Results of Operation. A. G. Morrow, E. H. Sharp and E. Braunwald. Circulation 18:1091-1104 (Dec.) 1958 [New York].

The authors report on 20 male and 10 female patients, between the ages of 4 and 39 years, with congenital aortic stenosis confirmed by the demonstration of a systolic pressure gradient between the left ventricle and a systemic artery. Of the 30 patients, 13 had valvular aortic stenosis, 8 had subvalvular stenosis, and in the remaining 9 patients the obstruction had not been localized. Seven of the 13 patients had anginal pain, 3 had a history of syncopal attacks, and 12 had dyspnea. Only one patient was entirely asymptomatic. Of the 8 patients with subvalvular stenosis, 4 had anginal pain, 2 had histories of syncope, and 6 had dyspnea. Two of the 8 patients were entirely asymptomatic. Every patient had a harsh systolic murmur and a thrill at the base of the heart. A high-pitched, decrescendo diastolic murmur along the left sternal border was also present in 4 of the 13 patients with valvular stenosis and in 4 of the 8 patients with subvalvular stenosis. The second heart sound in the aortic area was diminished in 8 of the 13 patients and in 3 of the 8 patients. Fluoroscopic and roentgenographic examinations of the heart revealed some degree of left ventricular enlargement in all but 3 of the 30 patients. Poststenotic dilatation of the aorta was a prominent feature in almost every patient. Angiocardiography was carried out in 11 patients and always revealed a thickened left ventricular wall and a small left ventricular cavity. Left heart catherization was performed by the transbronchial route in 19 patients. In the other 11 patients, particularly young children, left ventricular pressures were obtained by means of direct puncture of this chamber through the left side of the anterior chest wall. The aortic valve gradients,

i. e., the differences between simultaneous peak systolic pressures in the left ventricle and the aorta or a peripheral artery, ranged from 15 to 172 mm. Hg and averaged 82 mm. Hg. Right heart catherizations were carried out in 28 of the 30 patients; findings suggested encroachment by the enlarged left ventricle on the interventricular septum and right ventricular outflow tract.

Eighteen of the 30 patients were operated on at the surgical clinic of the National Heart Institute in Bethesda, Md. A closed transaortic or transventricular operation was performed on the first 4 patients; surgical intervention under direct vision with the aid of general hypothermia was carried out in the next 11 patients; and the last 3 patients were operated on with the aid of extracorporeal circulation and elective cardiac arrest with the patients at normal temperature. Thus, 14 of the 18 patients were operated on with direct exposure of the aortic valve. Three of the 18 patients died, one of irreversible ventricular fibrillation occurring after the period of inflow occlusion, one of septicemia produced by Pseudomonas organisms 5 weeks postoperatively, and one 10 days postoperatively of massive intrathoracic hemorrhage after the administration of heparin and bishydroxycoumarin (Dicumarol) given in the treatment of femoral thrombophlebitis. The 15 surviving patients are free of cardiovascular symptoms, but despite these gratifying clinical results, postoperative hemodynamic studies in all but 5 indicate that some degree of residual stenosis exists.

Ten years ago congenital aortic stenosis was generally considered to be uncommon and seldom to carry a grave prognosis. The severity of obstruction of left ventricular outflow could not be directly assessed, and suitable surgical procedures for its correction were not available. The changing concepts in respect to this malformation are reflected in these 30 patients. The lesion was found to be relatively common and frequently serious. The severity and site of obstruction could be precisely evaluated, and a physiological basis was provided for the selection of patients for operation providing direct exposure of the aortic valve.

Diagnosis and Treatment of Peripheral Round Infiltrates of the Lung. I. Andersen and B. Clausen. Acta. chir. scandinav. 115:422-426 (no. 6) 1958 (In English) [Stockholm].

The authors report on 52 patients with peripheral round infiltrates of the lung ("coin lesions"), in whom no more than a tentative clinical diagnosis was made and in whom the correct diagnosis was secured by exploratory thoracotomy. Of the 52 patients, 37 were men and 15 were women; 15 (6 women and 9 men) were less than 40 years old, and 37 (9 women and 28 men) were over 40 years of age. Thoracotomy revealed primary or secondary carcinoma in 3 patients (20%), aged less than 40 years, and in 25 patients (69%), over 40 years of age. Tuberculoma was found on surgical intervention in 8 patients (53%), aged less than 40 years, and in 5 patients (14%), over 40 years of age. Of the 52 patients, 17 underwent pneumonectomy; 17, lobectomy; 13, segmental resection; and 5, removal of pleural cysts, hamartoma, and meningocele. There were no operative deaths.

Because of the high incidence of malignant lesions in this series of patients with asymptomatic peripheral round infiltrates of the lung, prompt active surgical treatment is justified. From the form, size, and solidity of the tumor as visualized in plain chest roentgenograms and tomograms, nothing can be deduced except that the hamartomas are perhaps of less regular circular shape than the carcinomas and tuberculomas. The presence of calcification may be suggestive of tuberculoma or hamartoma but does not rule out a diagnosis of cancer. Degeneration may be seen in tuberculoma, in inflammatory processes, and in carcinoma. In most patients bronchography, bronchoscopy, and the study of aspirated bronchial secretion did not provide additional information. Because of the difficulties observed in the preoperative differential diagnosis, extensive use of exploratory thoracotomy is recommended, in the course of which frozen sections of biopsy specimens are subjected to microscopic examination. On the basis of the operative and microscopic findings, the authors determine the type and extent of the operation to be performed.

Clinical Application of a New Flexible Knitted Dacron Arterial Substitute. M. E. DeBakey, D. A. Cooley, E. S. Crawford and G. C. Morris Jr. Am. Surgeon 24:862-869 (Dec.) 1958 [Baltimore].

Since early in 1957 the authors have employed seamless knitted, cleansed but chemically untreated Dacron tubes, in different sizes and in the form of bifurcations as well as multibranch tubes, in the treatment of a wide variety of aortic and arterial diseases, such as occlusive disease of the abdominal aorta and iliac arteries and extensive fusiform aneurysm of the descending thoracic aorta. Analysis of this experience, which now includes a total of 737 cases, reveals results that are, in general, most satisfactory. Although insufficient time has elapsed to provide long-term evaluation of the functional efficacy of these grafts, follow-up observations for periods ranging from 1 to 1½ years have been most gratifying and within this period of time have revealed no failures which could be attributable to the graft. An aortogram made one year after surgical intervention in a patient with extensive arteriosclerotic aneurysm of the abdominal aorta involving the bifurcation and common iliac arteries showed excellent functioning of the bifurcation

Dacron graft used to replace the excised portion with the aortic aneurysm. An aortogram made 14 months after operation in another patient showed restoration of circulation in the right lower extremity by means of a bypass Dacron graft attached by end-to-side anastomoses to the common femoral artery above and to the popliteal artery below.

Moreover, a comparison of these results with those obtained by the authors in their previous experience with other types of synthetic vascular replacements and with homografts indicates the Dacron graft to be superior in all respects. Particularly noteworthy is the fact that the incidence of failure attributable to the graft was significantly less in the Dacron series than in other synthetic grafts. An important factor contributing to the reduction in deaths in the more recent Dacron series is improvement in surgical management resulting from increased experience. The fact remains, however, that the mortality in the Dacron series is significantly lower than in the other series, and this fact, along with the distinctly higher incidence of over-all successful results, provides good evidence of the clinical value and efficacy of the new arterial substitute.

Surgical Complications in a Community Hospital with Particular Reference to Wound Infections. P. J. Guthorn, H. A. Kazmann and Chang You Wu. J. M. Soc. New Jersey 55:650-655 (Dec.) 1958 [Trenton].

The study was begun in January, 1957, at the Monmouth Memorial Hospital in Long Branch, N. J. It was undertaken as part of a surgical residency program. On the ward service, where supervision was possible, an effort was made to search for all complications. Infections on the private service were studied with the cooperation of the attending staff. Two forms were used. One was a Report of Surgical Complications to be filled out weekly on each ward or unit. The responsible house officer checked in the appropriate column. The second was the Wound Infection Report, filled out by the house officer (or, in private cases, by the attending surgeon) and forwarded when the infection had run its course. On the ward service 264 operations were performed, with 15 surgical deaths; on the private service 1,895 operations, with 29 operative deaths. On the ward service a total of 130 complications occurred in 54 patients; forty complications occurred in the 15 ward patients who died within 30 days of operation, and 42 complications occurred in the 29 private patients who died after operation, showing that there is a tendency for complications to be multiple.

The morbidity and mortality on the ward service were higher than on the private service. Factors responsible for the higher incidence of complications on the ward are the greater age, the substantial proportion of patients who are malnourished, and the tendency to seek care late in the course of the disease. Since malnourishment and undernourishment are common among ward patients, a longer time was needed in elective surgery cases to correct nutritional, blood volume, and other disturbances. The tendency to seek medical care late was also evident in the patients admitted, almost moribund, with long-standing intestinal obstruction or chronic blood loss.

A total of 49 wound infections occurred, 16 in the 264 operations on ward patients and 33 in the 1,895 operations on private patients. Frequently the period of clinical quiescence was 10 to 12 days, and in 2 patients 21 and 24 days respectively. The principal offending organism was the hemolytic Staphylococcus pyogenes var. aureus. A total of 69 purulent infections were studied bacteriologically. All were mixed infections except for a few of the face and neck. The hemolytic Staph. aureus was present in 45 of these and the nonhemolytic Staph. aureus in 32. In smaller numbers the following organisms were found: Pseudomonas aeruginosa, Proteus vulgaris, Bacillus subtilis, Escherichia coli, nonhemolytic Staphylococcus albus, diphtheroids, Clostridium organisms, and hemolytic and nonhemolytic streptococci.

There were many gaps in the bacteriological study; for instance, phage typing either was not available or was not done in sufficient numbers to demonstrate a connection between the organisms encountered in the hospital and those in the wound infections. There was evidence that the incidence of wound infections appears to be increasing, and that wound infections tend to occur as small epidemics. There was a higher incidence of antibiotic resistance in the hospital infections, although the flora of both in-hospital and out-of-hospital infections are similar.

Primary Adenocarcinoma of the Appendix: Report of 16 Cases. Acta chir. scandinav. 115:447-456 (no. 6) 1958 (In English) [Stockholm].

The authors report on 9 women and 7 men with primary adenocarcinoma of the appendix. Thirteen of the 16 patients were over 50 years of age, 1 was 48 years old, and 2 were less than 40 years of age. The cases of these patients, who were treated at various Danish hospitals, were recorded at the Danish Cancer Registry in Copenhagen between 1943 and 1956. Most of the patients had clinical manifestations of appendicitis. Appendectomy was performed on 7 patients. Of these, 3 are still alive, without signs of recurrence, 2, 4, and 10 years after the surgical intervention. One patient died of peritonitis one week after the operation, and the remaining 3 died of recurrence 9 months, 2 years, and 3 years after the operation. Four patients were subjected to appendectomy followed by right-sided hemicolectomy after the lapse of 5, 19, 53, and 193 days. Three of these are still alive, without signs of recurrence, 21 months, 2 years, and 4½ years after the first admission. The fourth patient, who underwent hemicolectomy 6 months after the appendectomy at a time when cutaneous metastases in the operative scar had occurred and there was macroscopically visible recurrence at the site of the appendix, died of recurrence 12 months later. Of the remaining 5 patients, 2 died in the hospital after palliative surgical measures for ileus; 3 were not operated on, 2 of them being admitted in hopeless condition and dying within a few days and 1 dying of an abdominal tumor and ascites within 2 months after admission. In all the patients, the diagnosis of adenocarcinoma of the appendix was made only at operation or autopsy. Histologically the tumors showed the same structure as cancers of the colon.

Adenocarcinoma of the colonic type is the rarest and most malignant form of carcinoma of the appendix. The diagnosis cannot be made preoperatively but is established often as a surprise, by microscopic examination. Appendectomy can be regarded as adequate treatment only when the lesion is confined to the mucosa and is of peripheral localization; in all other cases, right-sided hemicolectomy is indicated. Recovery from malignant mucocele of the appendix may be achieved by appendectomy, provided that rupture of the appendix has not given rise to peritoneal pseudomyxoma. If this has occurred, as much as possible of the gelatinous material must be removed; if the cecum shows involvement, hemicolectomy must be performed. In the presence of a carcinoid tumor, which occurs about 10 times as frequently as carcinoma, appendectomy is sufficient.

Indications for Open Heart Surgery Using Temporary Cardiopulmonary Bypass. D. A. Cooley. J. Louisiana M. Soc. 110:407-410 (Dec.) 1958 [New Orleans].

Cooley reviews observations on 465 patients who, during the past 2½ years, were operated on with the aid of a pump oxygenator which permitted open cardiotomy during temporary cardiopulmonary bypass. Among these patients, who were treated at several hospitals in Houston, Texas, there were 392 with congenital and 73 with acquired lesions. The over-all mortality among the 164 patients operated on for ventricular septal defects was 18%. Age was an important factor in survival, the operative mortality being 40% among patients less than 2 years old and 7% among 100 patients ranging in age from 2 to 15 years. Since no deaths occurred in patients with normal or moderately elevated pulmonary arterial pressure, the author feels that almost all ventricular septal defects should be repaired.

Of the 123 patients with atrial septal defects, 90 had the ostium secundum type. The 6 deaths in this group concerned patients more than 25 years old and usually with advanced cardiopulmonary disease. The majority of patients less than 25 years old should be operated on if a significant left-to-right intracardiac shunt is present. Twenty patients with ostium primum defects were operated on, with 3 deaths. Seven deaths occurred in the 13 patients with canalis atrioventricularis communis. This complicated anomaly may be virtually incorrectible, but in many instances a satisfactory repair may be obtained.

Twenty-nine patients were operated on for the tetralogy of Fallot. In the acyanotic or minimally cyanosed patient with the tetralogy of Fallot, the results were comparable to the results in isolated ventricular septal defect. Among patients exhibiting severe cyanosis and diminutive pulmonary artery, the operative mortality was 40%. The author says that, in very small infants in critical condition from cyanotic spells, the anastomotic procedures of Blalock and Potts offer palliation. Risk of operation is low in congenital aortic and subaortic stenosis, 20 patients with this defect being operated on without a single death. Among 22 patients operated on for pulmonic valvular and infundibular stenosis, one died. Excellent results are obtained with open heart surgery in these lesions. Of 10 patients operated on for total anomaly of pulmonary venous drainage, 7 survived. The 3 deaths occurred in patients with complicating features making any form of surgical attack extremely risky. Complete repair was achieved in 3 patients with aorticopulmonary septal defect.

In 6 patients with transposition of the great vessels, surgical correction with use of the pump oxygenator was not successful. Poor results were obtained also in 15 patients with miscellaneous congenital defects, such as mitral atresia, single ventricle, tricuspid atresia, truncus arteriosus, and Ebstein's disease.

Those with acquired lesions who underwent open heart surgery included 24 with calcific aortic stenosis. The results of operation on these patients were encouraging. Regarding mitral stenosis, the author says that division of the commissures under direct vision permits accurate repair of the mitral stenosis and control of thrombi and embolism from the left atrium. This technique was used in 10 patients, all of whom had previously undergone closed commissurotomy. The procedure, which at present is reserved only for the recurrent lesions, may later be used for primary operations. All 4 patients subjected to operation for ventricular aneurysm after myocardial infarction survived with good functional results. Treatment was successful in 3 patients with cardiac myxoma. Good results were obtained also in 3 patients with stab wounds or blunt injuries of the heart.

Abdominal Repair of Hiatal Hernia: A Study of 138 Cases. E. S. Crawford and M. E. DeBakey. Am. Surgeon 24:889-895 (Dec.) 1958 [Baltimore].

The authors report on 138 patients with hiatal hernia who were treated surgically at the Jefferson Davis, Methodist, and Veterans Administration Hospitals in Houston, Texas, between 1951 and 1958. There were 72 men and 66 women, but, if the patients treated at the Veterans Administration Hospital are excluded, there were more women than men. The ages of the patients ranged from 32 to 85 years, with more than 33% being over 60 years of age. The transthoracic approach was used in 24 patients and the abdominal in 114. The transthoracic route was used in most of the early cases, but during the past 4 years this approach has been employed only in patients with other thoracic lesions. The increasing preference for repair of the hiatal hernia by the abdominal route has been caused by frequent association of the hiatal hernia with other lesions, such as cholelithiasis, duodenal ulcer, and leiomyoma of the intestine. In patients with such associated lesions, the latter may be surgically treated at the same time that the hernia is repaired if the abdominal route is employed. There were 57 abdominal lesions associated with hiatal hernia in the 114 patients subjected to abdominal repair; in addition, appendectomy was performed on 47 patients, gastrostomy and digital esophageal dilatation on 9, and bilateral lumbar sympathectomy on 1.

The technique employed for the abdominal repair of the hernia included an upper abdominal midline incision and exposure of the hiatal region by retraction of the liver medially and the stomach downward. Retraction of the stomach downward reduced the hernia and permitted exposure of the hiatus through an incision in the peritoneum between the esophagogastric junction and the diaphragm. This exposure was completed by encircling the esophagus with umbilical tape for traction and dissecting the retroperitoneal fibrofatty tissue from the lateral margins of the hiatus. The hiatus was reduced to normal size by approximating the lateral margins behind the esophagus and suturing the esophagogastric junction to the under surface of the new esophageal opening.

Two of the 138 patients died, and these 2 deaths occurred among the patients treated by transthoracic repair; one was due to myocardial infarction, and the other to disruption of the diaphragmatic incision. Hiatal hernias recurred in 2 patients subjected to thoracic repair and in 4 subjected to abdominal repair. Symptoms, such as burning pain, vomiting, regurgitation, hematemesis, melena, dysphagia, belching, and nausea, were relieved in all patients who had successful abdominal repair; however, of 3 patients subjected to thoracic repair, 2 later required cholecystectomy and 1 required gastrectomy for relief of symptoms. The effectiveness of the technique employed in the abdominal repair of hiatal hernias was evident in the extremely low incidence of recurrence (3.5%) and the safety with which it was combined with other abdominal procedures.

Adenomas of the Adrenal Cortex. M. M. Desyatov and M. G. Trachtenberg. Khirurgiya 34:35-41 (no. 10) 1958 (In Russian) [Moscow].

Modern methods of examining patients with endocrine diseases, such as suprarenopneumography, determination of urinary 17-ketosteroid concentration, and the cortisone test, facilitate the diagnosis of adrenal cortical adenoma. The authors present 20 case reports of patients with the Itsenko-Cushing syndrome. The patients were subjected to lumbotomy and excision of the tumor. The operation was carried out with the patient under oxygen-ether or spinal anesthesia. To prevent suprarenal insufficiency, the patients were treated preoperatively with preparations derived from the adrenal cortex—corticotropin (ACTH) and desoxycorticosterone acetate. Cortin and cortisone were given during the postoperative period. Two patients died. A stable positive effect was observed in the rest of the patients, and the clinical symptoms of this disease gradually disappeared. Women treated by this method began to menstruate again. Excessive hair on the face, body, and extremities disappeared. These women reduced in weight, their arterial blood pressure became stabilized, and they experienced no headaches or general weakness.

Contributions to the Pathological Anatomy of Thrombosis and Embolism. A. I. Strukov and N. N. Vasilieva. Khirurgiya 34:86-96 (no. 10) 1958 (In Russian) [Moscow].

The authors present a statistical analysis of thrombosis and embolism for 20 years (1938-1957), based on data of the department of pathological anatomy of the Sechenov Medical Institute in Moscow. Fourteen thousand eight hundred fifty-three autopsies were performed during that period, and 128 embolisms of the pulmonary artery (0.86%) were recorded. The incidence of this complication rose in the years between 1940 and 1954 from 0.91 to 3.92% but was totally absent during the war period (1942-1945). This confirms the observations of foreign authors. The rise in the incidence of thromboembolism of the pulmonary artery coincides with the increase in the percentage of tumors and diseases of the cardiovascular system as the cause of death. The distribution of thrombosis and embolism among different nosological forms demonstrated that the first place is occupied by diseases of the cardiovascular system, constituting 56% of the thromboses and 37% of all the thromboembolisms of the pulmonary artery. The incidence of thrombosis and embolism among patients with tumors of various localizations appeared to be lower than among those with diseases of the cardiovascular system. The absolute number of thromboses and embolisms in the group of tumors is still high (26% of all thromboses, 38% of all thromboembolisms of the pulmonary artery). The veins of the lower extremities, the right heart (especially the right auricular appendage), and the veins of the small pelvis constitute the source of thromboembolism of the pulmonary artery. The authors recommend the use of anticoagulants in the treatment and in the prophylaxis of thromboembolism of the pulmonary artery.

Modern Therapy of Blood Coagulation Disturbances. D. M. Grozdova and V. A. Agranenko. Khirurgiya 34:101-108 (no. 10) 1958 (In Russian) [Moscow].

The use of anticoagulants in surgical clinics has a pronounced therapeutic effect in the acute and subacute stages of thrombosis and thrombophlebitis. In the treatment of acute thrombosis and of thrombophlebitis, the most rational method is the administration of preparations of the heparin and coumarin groups. The most effective method of treatment, which makes possible prevention of recurrence of the disease and of various complications, is the surgical treatment of thrombophlebitis. Anticoagulant therapy is indicated after surgical treatment of thrombophlebitic splenomegaly, portal hypertension, and diseases in which splenectomy or vascular anastomosis is required. This therapy decreases the danger of postoperative thrombosis. Intravenous injection of heparin is most effective in acute stages of thrombosis. Intramuscular injections of heparin at intervals of 6 to 12 hours prolong its action. Prolonged anticoagulant therapy is indicated in the recurrent form of thrombophlebitis of the extremities and in patients with a history of myocardial or pulmonary infarction. This treatment is conducted under control of the prothrombin concentration (65-80%). The authors' observations of such prolonged therapy (from 2 months to 2 years) showed the absence of recurrence of the disease or of untoward side-effects due to the administration of the anticoagulant drug.

Hematological Changes After Total Gastrectomy. W. Kothe. Beitr. klin. Chir. 197:184-191 (no. 2) 1958 (In German) [Munich].

Total gastrectomy was performed on 59 of 1,083 patients with carcinoma of the stomach at the Karl Marx University of Leipzig between 1945 and 1956. The 40 patients who have survived from 1 to more than 4 years have all required special care, because, with total loss of the stomach, metabolic as well as hematological changes can be expected. Literature reports on blood changes after total gastrectomy are mentioned, and the author describes studies of iron metabolism, by means of iron tolerance tests, on 21 patients on whom gastrectomy had been performed up to 4½ years previously. There was evidence that iron resorption becomes impaired after total gastrectomy.

Total loss of the stomach generally produces hematological changes, which progress in phases from hypochromic anemia to megalocytic anemia of half-pernicious character to true pernicious anemia. The time of appearance of each phase differs, as it is not entirely dependent on the duration of absence of the stomach. After a patient has survived total gastrectomy for 3 years, the blood picture (the peripheral and the bone marrow punctate) should be examined at intervals of 3 months, because the author found that the development of pernicious anemia may take place within a few months.

Surgico-Angiological Problems in Diabetes Mellitus. G. Meyer-Burgdorff and E. Kricke. Beitr. klin. Chir. 197:139-151 (no. 2) 1958 (In German) [Munich].

The authors are concerned with whether the vascular lesions of diabetes mellitus represent a special form of angiological disease. The question is raised whether the metabolic disorder or the treatment with insulin is the decisive factor in the pathogenesis. Although specific diabetic changes in the structure of the vascular walls have not been demonstrated, numerous factors have been cited to show that "diabetic angiopathy" does represent a special form. It is characterized by premature sclerosis, particularly of the terminal vessels, and the resulting stasis leads to secondary changes in the conveyor arteries. The capillary damage, as a rule, appears only after the diabetic disorder has existed for from 5 to 15 years, but sometimes very severe forms of vascular disease are observed in young diabetic patients. Although some investigators include only nephropathy (Kimmelstiel-Wilson disease) and retinopathy in the concept of "diabetic angiopathy," others also include gangrene of the extremities, and this last form is of particular interest to the surgeon. The authors cite figures to demonstrate the high incidence of gangrene of the extremities in diabetics.

In discussing the influence of insulin on the blood perfusion of various tissues, the work of several investigators on this problem and that of one of the authors are cited. The observed increased blood perfusion of the muscles of diabetics indicates increased capillarization, and the blood perfusion of these capillaries is further increased by insulin. The increased blood perfusion of the muscles apparently is at the expense of the blood perfusion of the skin. Deficient circulation in the skin, however, is likely to cause necrosis and gangrene, and since insulin acts chiefly on the muscles, it may be regarded as indirectly responsible for gangrene, rather than as having a retarding effect on the development of that condition.

Since exclusion of the sympathetic system promotes the blood perfusion of the skin, the authors advocate sympathectomy for the prevention of diabetic gangrene. They report their observation on 61 diabetic patients with vascular complications in the extremities. Twenty-two of 42 patients who had received conservative treatment and 10 of 19 who had been subjected to sympathetectomy required subsequent amputation, that is, the same percentage in both groups. However, taking into account the level of the amputation, it was found that, whereas 80% of the amputations after conservative treatment were extensive, only 33% of those after sympathectomy were extensive. This indicates that sympathectomy in diabetics during the stage of necrosis shifts the level of the amputation in the distal direction. The authors advocate sympathectomy as a prophylactic measure against gangrene of the extremities in diabetic patients.

Multiple Hemangiomas of the Jejunum as a Cause of Massive Gastrointestinal Bleeding.

A. L. Evans, O. S. Cofer and H. H. Gregory. J. M. A. Georgia 47:600-603 (Dec.) 1958 [Atlanta].

The authors cite figures from the literature, which prove the extreme rarity of hemangiomas of the small intestine, and present the history of a male patient who had had no intestinal bleeding until he was 61 years old. When hospitalized at age 63, in July, 1957, this patient complained of epigastric discomfort and bleeding from the rectum. He stated that approximately 2 years prior to admission, while at stool, he passed large amounts of bright red blood through the rectum. He became so weak that he fainted. After that time, at about 2-month intervals, he had other similar episodes. He had been thoroughly examined by several physicians and at 2 university clinics and was told that all x-ray, sigmoidoscopic, and fecal examinations were negative. He was advised to have an exploratory laparotomy but refused. Eight months prior to admission he began to have constant epigastric pain of a burning nature, which radiated under his ribs and sternum. He was treated for this with a bland diet and antacids with little relief. The pain had become progressively worse and was constant day and night. It had no relation to meals but was aggravated by deep breathing or stooping over. After thorough examination the patient was told that the cause of bleeding could not be located and was advised to have an exploratory laparotomy. On the 5th day after admission he had severe melena and consented to surgical exploration.

The small intestine was explored first, and at the ileocecal area and along the ileum small bluish nodules were noted. As the jejunum was approached, these became more numerous. The proximal jejunum was studded with numerous bluish nodules, varying in size from 3 to 16 mm. (matchhead to size of a dime). Examination of the stomach, liver, colon, and other abdominal viscera failed to reveal further tumors. It was decided to resect only the proximal part of the jejunum in the hope that the bleeding had arisen from the larger tumors; the proximal 90 cm. of the jejunum, beginning 3 cm. distal to the ligament of Treitz, was resected. An end-to-end jejunojejunostomy was done. The postoperative course was uneventful. Examination of the specimen disclosed that the background of the bluish nodules was that of cavernous hemangiomas in the submucosa. There was no evidence of malignancy. The patient experienced further hemorrhages, requiring blood replacement after the operation. Since the entire small intestine cannot be removed, it was hoped that another look might uncover the chief area of bleeding or that multiple mural excisions could be considered.

The commonest presenting symptom of multiple hemangiomas of the small intestine is bleeding from the rectum. A few cases have been reported in which there was intestinal obstruction or intussusception, and occasionally inflammation of the tumor simulated appendicitis. In some cases, these intestinal hemangiomas cause only vague abdominal symptoms. Large hemangiomas may be diagnosed preoperatively by characteristic phleboliths in the roentgenogram. The diagnosis is usually made by exploratory laparotomy or at autopsy. Repeated melena with unexplained anemia or numerous hemangiomas of the skin should arouse suspicion of intestinal hemangioma. The patient presented had a hemangioma on the lip. Hemangiomas should be considered before doing a "blind" gastric resection. The treatment is surgical; results are excellent in single lesions, poorer in multiple lesions.

Cause of Death in Surgery of the Newborn: Emphasis on Prevention of Aspiration.

R. Spencer. J. Louisiana M. Soc. 110:418-422 (Dec.) 1958 [New Orleans].

This report is concerned with 74 infants, less than 1 month of age, who in the course of the last 3 years were observed on the pediatric surgery service of the Charity Hospital of Louisiana in New Orleans. Twenty-eight of these 74 infants died. This study includes all the infants who were operated on, or whose condition was diagnosed as being a surgical one, on or before the 30th day of postnatal life. Twenty-one of 37 infants with early congenital anomalies died. Their average age at operation was 4 days. More than half of the deaths were due to pulmonary complications—atelectasis and pneumonitis. The anomalies in this group were congenital obstructive lesions of the alimentary tract, perforation of the stomach as a result of an abnormality in development, omphalocele, Siamese twins, and multicystic kidney. There were no deaths among the 17 patients with late congenital anomalies, which included pyloric stenosis, incarcerated inguinal hernia, and Hirschsprung's disease. The average age of these infants was 23 days.

All 6 infants with noncongenital emergencies early in the neonatal period died. This group included 2 infants with paralytic ileus due to sepsis, a 9-day-old, 900-Gm. (2-lb.) baby with a bleeding gastric ulcer, and 3 1,400-Gm. (3-lb.) infants with a condition labeled constipation-dehydration. These dehydrated patients apparently died of intestinal obstruction produced by plugs of inspissated milk curds. At autopsy there was increased fibrosis in the pancreas of one of these patients. All 3 infants treated for trauma survived. The only death among 11 infants with miscellaneous conditions concerned a 3-week-old baby with a cystic hygroma of the axilla, who had diarrhea, then pneumonia, and finally died of viral hepatitis and septicemia due to Escherichia coli 13 days after operation.

The deaths due to multiple congenital anomalies were mostly unavoidable, but the largest group of deaths, those due to pulmonary complications, should be preventable. The most important factor in prevention of death from aspiration is early diagnosis and treatment of congenital obstructive lesions of the alimentary tract. Any infant who is difficult to resuscitate at birth or who has intermittent cyanosis and excessive mucus should be suspected of having atresia of the esophagus with tracheoesophageal fistula until the diagnosis has been excluded by passing a catheter through the esophagus and into the stomach. Every newborn infant who vomits, particularly if the vomitus contains bile, should be subjected to roentgenoscopy of the abdomen to rule out congenital intestinal obstruction. If tracheoesophageal fistula with esophageal atresia is suspected because of inability to insert a nasogastric tube, the diagnosis should be confirmed by fluoroscopy.

Once the diagnosis of intestinal obstruction is made, x-ray studies with contrast material are contraindicated. The infant should be placed on his abdomen, and decompression of the gastrointestinal tract should be undertaken. In these small patients the ordinary urethral catheter is superior to the Levin tube. Gravity drainage and intermittent aspiration of the catheter with a syringe are preferable to strong constant suction. Preoperative decompression of the gastrointestinal tract cannot be overemphasized. Frequent suction of the nasopharynx is almost as important in intestinal obstruction as in tracheoesophageal fistula. Newborn infants have poor cough reflexes and many aspirate the increased secretions resulting from the irritation of the nasogastric tube. Additional preoperative measures for both tracheoesophageal fistula and intestinal obstruction include minimal but adequate hydration, transfusion if necessary, antibiotics, and administration of an adequate drying agent before induction of anesthesia. The smaller the infant, the more important is this last measure.

Postoperatively, all these patients require an atmosphere of high humidity, suction of the nasopharynx, and the prone position. Even with the most expert nursing care, these tiny patients, who have poor gag and cough reflexes, will often aspirate secretions—usually with disastrous results. For this reason, gastrostomy is recommended in congenital intestinal obstruction.

NEUROLOGY & PSYCHIATRY

Horse Serum Neuropathy. A. A. Marinacci. Bull. Los Angeles Neurol. Soc. 23:149-159 (Dec.) 1958 [Los Angeles].

This study is concerned with electromyographic studies on 115 patients who had muscular paralysis in the region of the shoulder girdle and arms. These patients had received serum therapy in the form of tetanus antitoxin for lacerations or deep wounds. Electromyographic studies demonstrated that this horse serum plexitis can be misinterpreted and that other disease entities have been falsely incriminated. This results because the disorder has a latent period of from 6 to 12 days after the injection of antitoxin. When the paralysis appears a week or 2 after the injection, the serum therapy has usually been forgotten. Another important fact is that the paralysis usually is focal and may involve either a group of muscles supplied by a single peripheral nerve or the group of muscular structures innervated from the fifth cervical nerve root or an isolated peripheral nerve such as the axillary nerve.

Electromyography proved valuable not only in revealing the true nature of this neuropathy but also in differentiating it from other diseases. Electromyographic studies revealed more widespread involvement than did the clinical signs. It was found that the roots and trunks of the brachial plexus are rarely involved and that its cords are only occasionally affected. The damage is largely limited to the proximal peripheral nerves which have their immediate origin from the roots of the brachial plexus, such as the dorsal scapular and long thoracic nerve of Bell, from the trunks, such as the subclavian and suprascapular nerves, or from the cords, such as the medial and lateral anterior thoracic, subscapular, thoracodorsal, axillary, and musculocutaneous nerves. The terminal branches of the cervical plexus are also affected, while the radial, median, and ulnar nerves are rarely involved directly. Occasionally involvement of either the radial, median, or ulnar nerves may be seen. However, the involvement in these nerves is due to pressure on the nerve while the patient is in bed and not due directly to the horse serum itself. The most commonly affected nerve is the axillary, next the suprascapular, then the musculocutaneous, the cervical plexus, and the long thoracic nerve, and finally the dorsal scapular.

This neuropathy resembles several other conditions, particularly anterior poliomyelitis, cervical cord tumor, amyotrophic lateral sclerosis, cervical cord trauma, cervical nerve root compression, a lesion of the upper trunk of the brachial plexus, shoulder-hand syndrome, and finally cerebral vascular accident. The peripheral effects of this disease entity are further substantiated by its favorable prognosis for complete recovery from the paralysis. It is the author's opinion that this disease should be designated as a horse serum neuropathy rather than as a horse serum "plexitis," because the plexus per se is not involved in the majority of instances. Finally, because horse serum neuropathy stems from trauma, the electromyogram makes clear its relationship to an industrial as well as a medicolegal prognosis, especially when the patients are observed for as long as 3 years.

Routine Blood Control on Permanent Treatment with Mesantoin and Dimedion. E. Kjøboe and E. Kroman. Nord. med. 60:1599-1602 (Nov. 6) 1958 (In Danish) [Stockholm].

In 59 patients treated with Dimedion and in 110 treated with Mesantoin, the treatment was usually started during hospitalization and continued after the patient was made ambulant. Leukocyte and differential blood counts were carried out 2 to 4 times a month during the first 2 months, then, as a rule, once monthly. In view of the grave prognosis in granulocytopenia, patients treated with substances which can cause this complication should be given reasonable safety. In 3 cases of granulocytopenia, with 200 or fewer granulocytes per cubic millimeter, originated during treatment with Mesantoin or Dimedion, the granulocyte count had gradually diminished during the preceding weeks. Routine blood control at 4-week intervals is believed essentially to increase the chance of demonstrating a beginning granulocytopenia. In many cases an apparently harmless granulocytopenia will be found, with spontaneous remission, but such a finding should always occasion repeated blood cell counts at short intervals if administration of the preparation in question is continued. Clinical observation and instruction of patients as to the symptoms in severe granulocytopenia (fever, sore throat, tendency to abnormal bleeding) are necessary but not sufficient, since a severe granulocytopenia can appear without clinical symptoms. Treatment with Mesantoin and Dimedion should be introduced only when other antiepileptics have been tried.

Hydrosaline Disorders in Familial Periodic Paralysis. M. Espinar Lafuente, A. Sánchez Agesta, J. Díaz Nogales and E. de Landázuri. Rev. clín. españ. 71:86-92 (Oct. 31) 1958 (In Spanish) [Madrid].

A man, 26 years old, was hospitalized at the medical clinic of the University of Granada, requesting treatment for recurrent crises of familial periodic paralysis from which he had been suffering for the past 6 years. The paralytic crises were more or less severe, involving mainly the legs and to a moderate extent the arms and being associated with nausea and vomiting. They subsided within 24 hours, leaving a sensation of great muscular weakness in the limbs. The clinical and biochemical examination of the patient in the periods when he was free from these attacks gave normal results.

In studying this patient, an artificial paralytic crisis was induced by the intramuscular injection of desoxycorticosterone acetate (DOCA) which was administered at 12-hour intervals in doses of 10 mg. per injection up to a total of 5 injections. The crisis appeared 9 hours after the 5th injection of DOCA. It lasted 30 hours, after which the sensation of muscular weakness was reported by the patient. The stage of induction of the crisis lasted 6 hours (2 before and 4 after paralysis was established). It was marked by hypopotassemia, hypernatremia, and abundant diuresis, the urine containing a large quantity of sodium. The sodium-potassium ratio was high and became still higher during the peak of paralysis which lasted 24 hours. This stage was marked by a progressive lowering of sodium and potassium blood levels, the sodium returning to a normal value and the potassium to a still lower figure. Recovery was marked by profuse diuresis, with a large quantity of sodium in the urine and a moderate amount of potassium. The sodium-potassium ratio was increased, with the potassium blood level returning to normal. This stage was prolonged for several hours after termination of the crisis. Normal elimination of potassium in the urine and normalization of the sodium-potassium ratio occurred on the second day after termination of the crisis. Calcium and creatinine in the blood were at normal levels.

The authors believe that their observations in this case, and those previously reported in the literature, confirm the fact that crises of familial periodic paralysis are due to disorders of the metabolism of electrolytes and water, with consequent primary sequestration of potassium in the cells of the skeletal muscles and secondary sequestration of sodium.

Suicide and the Medical Community. J. A. Motto and C. Greene. A. M. A. Arch. Neurol. & Psychiat. 80:776-781 (Dec.) 1958 [Chicago].

The authors investigated the degree of contact that suicidal persons had with the medical community, before making a suicide attempt, in 175 consecutive suicides and in 197 unsuccessful suicide attempts in San Francisco between November, 1956, and September, 1957. At least 74 (42%) of the persons who committed suicide and 116 (60%) of those who attempted suicide were under medical care or had been so during the 6 months preceding the suicidal act. The physicians involved in the reports of the 372 persons represented all major medical specialties, except pediatrics; psychiatrists, general practitioners, and internists accounted for 47% of the 227 physicians known to have treated these patients. The patients complained most frequently of nervousness, depression, insomnia, abdominal distress, headache, apprehension, and seizures. Routine postoperative follow-up and antepartum and postpartum care also demanded attention as situations preceding a suicide attempt. Of the 372 persons, 84 (23%) had been in touch with a physician for at least a month before the suicidal act. Fifty-nine persons (16%) committed the act within a week of the last medical contact, and 14 (4%) had done so on the same day the physician was seen. Another 147 persons (40%) had seen a physician within 6 months of the suicidal act. Thus, the medical community is seen to be extensively involved in the suicide problem. The degree and kind of contact between members of the medical community and suicidal persons, and especially the physician's anxieties about suicide, are suggested as factors that should be studied further in assessing the physician's role in suicide prevention.

Psychic Symptoms in "Asia Disease." F. Askevold and A. Skulstad. Tidsskr. norske laegefor. 78:1066-1067 (Nov. 1) 1958 (In Norwegian) [Oslo].

Eight cases are described in which the psychiatric illness, for which the patient was admitted, seemed to develop after an acute febrile disorder in the fall of 1957, regarded as Asian influenza. In 4 patients episodes of mental symptoms had occurred previously, and hence the Asian influenza was considered as a precipitating factor. In 2 patients with protracted convalescence antibodies against the virus of Asian influenza could not be demonstrated. In 2 patients there was evidence of encephalitis, with marked schizophreniform symptoms.

GYNECOLOGY & OBSTETRICS

Chlorothiazide in Edema of Pregnancy. R. Landesman, R. N. Ollstein and K. J. Quinton. New York J. Med. 59:66-70 (Jan. 1) 1959 [New York].

Chlorothiazide (Diuril) was given to 100 pregnant women with edema in the toxemia clinic of the New York Lying-In Hospital. Of the 100 patients, 17 had preeclampsia, 27 had chronic hypertension without superimposition of acute toxemia, 16 had superimposition of acute toxemia, and 40 were normal. The drug was administered orally in doses ranging from 0.5 to 1.5 Gm. per day, the usual amount being 1 Gm. per day, given in divided doses of 0.5 Gm. The first tablet was given on arising and the second tablet in the afternoon so as to afford the patient an uninterrupted sleep, since the diuresis was then usually completed before retiring. The usual course of therapy was 7 days. However, some patients received chlorothiazide daily for several months. In rare cases administration of 1 Gm. of the drug per day produced nausea sufficient to require reduction in dosage to 0.5 Gm. per day with subsequent disappearance of symptoms. When diuresis did not follow the administration of 1 Gm. of chlorothiazide per day, the dose of the drug was increased to 1.5 Gm. per day. Seventeen patients received 1 mg. of reserpine daily, together with chlorothiazide. Four patients received 250 mg. of acetazolamide (Diamox) per day for one week.

All the patients responded to chlorothiazide with an initial weight loss, most marked during the first week of therapy. In the presence of clinically detectable edema, the agent was universally effective. The response was about proportional to the amount of edema initially present. Some patients showed an initial weight loss, but on prolonged therapy the diuretic response lessened, and a gain in weight occurred. In most patients diuresis diminished on sustained therapy when an apparent low-weight level was reached. Further increase in dosage had no effect in promoting diuresis. None of the patients accumulated massive edema fluid while receiving the drug. The patients with uncomplicated chronic hypertension showed a significant drop in blood pressure in response to chlorothiazide. The combination of chlorothiazide and reserpine appeared to enhance the hypotensive effect. With the onset of an acute process the antihypertensive effect of chlorothiazide was negligible when at all present. Chlorothiazide did not display apparent ability to reverse the toxemic process, since it did not reduce either fetal loss or the incidence of small babies. Chlorothiazide is a safe, potent, orally administered diuretic. The optimum daily dose is 0.5 Gm. given twice daily. On a balanced low-salt diet, chlorothiazide may be administered for periods up to 4 months without significant toxicity resulting to mother or fetus.

Problems in Diagnosis and Causes of Hirsutism. M. J. Fairweather and J. W. Goldzieher. J. Am. M. Women's A. 13:501-509 (Dec.) 1958 [New York].

The classification of the causes of hirsutism in women presented by the authors lists 4 principal groups: (1) adrenal causes, which include hyperplasia and adenoma and carcinoma of the adrenals; (2) ovarian causes, which include (*a*) different masculinizing tumors, such as arrhenoblastoma, adrenal rest type (masculinovoblastoma), hilus-cell Leydig-cell tumor, and luteoma and (*b*) the Stein-Leventhal syndrome; (3) familial form of hirsutism, without recognizable endocrine disorder; and (4) iatrogenic form (induced by androgen therapy). To explain the endocrine basis of hirsutism in adrenal hyperplasia, the authors discuss the mechanism of the pituitary-adrenal axis. They also mention the newer techniques of urinary steroid studies and the range of 17-ketosteroids under normal conditions and in the various conditions that may lead to hirsutism.

To illustrate situations that may be observed in the differential diagnosis of hirsutism, the histories of 6 patients are presented. The first patient, a 33-year-old woman, had adrenal cortical hyperfunction (Cushing's syndrome) with marked hirsutism. Adrenalectomy was performed on the left gland, and a gray encapsulated tumor, measuring 10 cm. in diameter, was removed. Histologically, the tumor cells resembled those of the adrenal cortex. Five months after the operation the patient felt well, and since then has given birth to 4 living infants. In the second patient, in whom hirsutism resulted from an adrenal rest tumor of the ovary, a large (8 by 8 cm.), pedunculated, nodular tumor of the left ovary was removed. The third patient had the Stein-Leventhal syndrome, showing round face, beard, and extreme degree of frontoparietal baldness. At operation, the uterus was found to be 3 or 4 times the normal size, and the ovaries appeared large and cystic. The uterus, tubes, and ovaries were removed. Under ordinary circumstances, that is, in the absence of uterine carcinoma, wedge resection of the ovaries is usually sufficient in the large majority of women with the Stein-Leventhal syndrome.

In the fourth patient, a 60-year-old woman, exploration of the pelvis revealed a pedunculated fibroid on the uterine fundus and an intramural fibroid on the right side of the fundus. The ovaries were bound down, small, and atrophic. After myomectomy a bilateral salpingo-oophorectomy was done. The patient bled briskly, and the blood pressure fell but was restored with levarterenol bitartrate. As the bleeding could not be controlled, a hysterectomy was performed. The patient was discharged from the hospital on the 9th postoperative day. Microscopic sections revealed a small ovarian tumor nodule, composed of small lobules containing oval-to-round hyperchromic and vesicular nucleated cells with light gray to pink cytoplasm. These were diagnosed as Leydig-cell rests. The history of the fifth patient, a 25-year-old woman, illustrates the difficulties encountered in making the diagnosis of familial hirsutism. This patient had a family history of excess hair growth and, although showing some menstrual disturbance, gave evidence of ovulation. On the basis of urinary steroid studies, the authors conclude that a mild degree of adrenal hyperplasia was present, superimposed on a strong family history of hirsutism. The sixth patient had adrenal hyperplasia that responded to cortisone therapy.

Primary Cancer of the Vulva. Ann. chir. et gynaec. Fenniae (supp. 5) 47:17-29, 1958 (In English) [Helsinki].

A series of 182 patients with primary carcinoma of the vulva were treated at the Institute of Radiotherapy, University of Helsinki. The patients were classified into 2 groups: one consisted of 153 patients who had not received treatment prior to their admission to the institute, and the other consisted of 29 patients who had had treatment at another hospital. The patients of the first group presented different stages of the disease; in one-fourth of the patients it was too widespread to attempt any therapeutic measure. Several patients of the second group had cancer, grade 1. Relapses and metastases occurred in more than one-half of the patients. Of the 153 patients belonging to the first group, 116 were amenable to treatment, and 98 of these were subjected to local electrocoagulation. The inguinal lymph nodes were treated by means of teleradium therapy or roentgenotherapy in two-thirds of the patients, but no such treatment was applied to this region in the remaining one-third. The 5-year survival rate was 36.1% among the 98 patients who were subjected to electrocoagulation, 27.5% among the 153 patients who had had no treatment before admission, 42.1% among the 145 treated patients, and 60.5 to 65.5% among the patients with cancer, grade 1. In addition to electrocoagulation, other local treatments, such as surgical extirpation of the tumor, treatment by means of a radium plate or by intubating radium needles, teleradium therapy, or roentgenotherapy, have also been used. This study illustrates the importance of early treatment of patients with carcinoma of the vulva, which constitutes no exception from other types of carcinoma.

Formal Carcinogenesis in the Uterine Cervix. H. G. Hillemanns. Arch. Gynäk. 191:235-270 (No. 3) 1958 (In German) [Munich, Germany].

The formal genesis of beginning tumor growth is just as problematical as is its causation. The question whether certain tissue changes are neoplastic or preneoplastic is of fundamental importance for the evaluation of the surface carcinoma of the uterine cervix. It is closely allied to two other questions, namely, whether this cancer must be traced to unicentric germination of the tumor anlage or to multicentric foci, and whether one is to expect a monophasic or a polyphasic growth. The author traces the various steps in the formal carcinogenesis in the uterine cervix. He himself performed all histological studies on material obtained from the clinic and from a cancer detection center in connection with colposcopic and cytological studies at the women's clinic of the University of Freiburg. In the course of the 5 years from 1953 to 1957, studies were made on 84 surface carcinomas, 24 microcarcinomas, and 638 cervical carcinomas in stages 1 to 4 (including microcarcinomas); also in 30 cases with unstable epithelium and in 26 with atypical epithelium, cases which are being watched and are still inconclusive.

The simultaneous appearance of surface carcinomas with erythroplasia, as well as similar local conditions on the external female genitalia, justifies the classification of surface carcinoma as a precancerosis. With exact observation, multicentric development can be demonstrated in 25% of the cases. In the majority of cases carcinogenesis is a unilocular process at the epithelial border of the cervix. Multiple genesis corresponds to the results of experimental cancer production and coincides with the field theory described by Willis in 1944-1945 and in 1953. The author mentions the possibility of the appearance of multicentric foci, as well as the misinterpretation of recurrences and metastases.

The tumor anlage is of multicellular origin; this is proved by multicentric foci and varying types of carcinoma on adjoining matrixes. Whether further dissemination takes place only by proliferation or also by inductive modification is still being discussed. As is proved by the study of microcarcinomas, the growth of true cancer originates from several sites of the preneoblastic surface epithelium, that is, it is pluricentric. Experimental tumor formation takes place in several phases and resembles a gradual dedifferentiation. Biphasic growth can be proved in cervical cancer as it has been in the dermatological precanceroses.

Biological studies demonstrated that the transition from the normal-appearing to the cancerously degenerated cell takes place gradually over a period of time, not in sudden leaps; the process can be followed morphologically. Cancer formation in the cervix is likewise a chronic process with prolonged latency. However, after a certain threshold value has been reached, infiltration occurs in a short time. On the basis of his own experiences and of the critical evaluation of previous reports, the author believes that, as regards the cervix, the morphologically monophasic carcinoma, developing directly and without latency, is without significance. Spontaneous regressibility of a surface carcinoma (established on the basis of strict criteria) does not seem to have been proved, and can be expected only after a change in the milieu.

The author emphasizes the decisive importance of the method of securing and processing tissues for the evalution of the growth of cervical carcinoma. After commenting on pathological and gynecologic viewpoints, he assumes a gradual increase in the malignancy in cervical carcinoma, in accordance with the biphasic mechanism in experimental carcinogenesis and with the demand for multiple cancer cells for tumor formation. In Druckrey's scheme of precancerosis, surface carcinoma is defined as the early stage of a malignant process which is still of purely cellular character.

Detergents in the Treatment of Leukorrhea. P. Godts. Belg. tijdschr. geneesk. 14:1085-1092 (Nov. 15) 1958 (In Flemish) [Leuven, Belgium].

According to Godts, detergents are widely used in the treatment of leukorrhea resulting from vaginal infections. He defines detergents as substances capable of reducing the surface tension of water, and discusses their characteristics. After describing the isolation of Candida albicans from the vaginal smears of patients with leukorrhea, he reports studies on the effects of various solutions of the detergents, Sabenyl and Neo-Sabenyl, on cultures of C. albicans isolated from such smears. The therapeutic use of detergents consists in, first, cleansing the vagina with a tampon containing a detergent solution; then a tampon that has been saturated with 5% solution of detergent is inserted into the vagina and is left in place for from 12 to 24 hours; this is followed by daily vaginal irrigations with a detergent solution for one week.

The 90 patients with leukorrheal vaginitis, treated with detergents and reviewed in this paper, included 30 with infections due to C. albicans (which are especially frequent in pregnant women), 30 with trichomoniasis, and 30 with mixed infections. Although the importance of Trichomonas vaginalis as a cause of infection has not been definitely established, when these parasites disappear from the vagina secretions after treatment, the clinical symptoms subside. The term "mixed infection vaginitis" was applied when either, both, or neither of C. albicans and T. vaginalis are found together with bacterial organisms. Treatment with detergents produced excellent results in 71 of the 90 patients—in 26 of those with moniliasis (C. albicans), in 24 of those with trichomoniasis, and in 21 of those with mixed infections. Good results were obtained in 9 additional patients (including 5 with mixed infections), whereas in the other 10 patients the effects of treatment with detergents were poor. On the basis of these results, the author recommends the use of detergents in the aforementioned forms of leukorrheal vaginitis.

Clinical Significance of the Enzymatic Study of the Ascitic Fluid in Maligant Tumors of the Ovary. G. Santoni. Minerva ginec. **10**:677-681 (Sept. 15) 1958 (In Italian) [Turin, Italy].

The author studied the lactic dehydrogenase activity in the ascitic fluid of 15 women with malignant tumor of the ovary, in 10 women with no tumor, and in some normal women. The values of this activity in the ascitic fluid of the 15 women with ovarian tumor were much higher than the values obtained in patients without tumor and in the normal women. The author believes that the lactic dehydrogenase activity is the result of the enzyme present in the necrotic parts of neoplastic tissue. The high lactic dehydrogenase activity, in fact, was present in patients with malignant tumor of the ovary already in an advanced stage. The values of the lactic dehydrogenase activity in the blood serum of women with malignant tumor of the ovary were found to be lower than the values of this activity in the ascitic fluid; therefore, the author believes that the enzyme present in the ascitic fluid does not derive from the blood.

The Conservative Operation for Endometriosis: A Report of Its Use in 200 Cases. L. A. Gray. J. Kentucky M. A. **56**:1219-1225 (Dec.) 1958 [Louisville].

The author reports on 200 women, between the ages of 18 and 40 years, who underwent the conservative operation for endometriosis. One hundred fifty-three patients (76.5%) were less than 30 years of age. Forty-seven patients were unmarried, 153 were married, and 28 (18.3%) of the latter had had children previously. The chief complaints of the patients were dysmenorrhea in 86.5%, sterility in 50.5%, intermenstrual pelvic pain in 33%, menometrorrhagia in 32.5%, and dyspareunia in 25.5%. One hundred twenty-nine patients (64.5%) had retroversion of the uterus. The conservative operation for endometriosis is a distinct one in gynecology, including dilatation of the cervix and curettage, excision of endometrial implants, resection of endometrial cysts, and suspension of the uterus. The approach was through a midline incision. Presacral neurectomy was performed in 44 patients (22%) who had the more severe dysmenorrhea. Myomas were excised in 31 patients. Modified Gilliam suspension of the uterus was performed on 178 patients.

There were no deaths and no obstructions. Subsequently 57 of the 200 patients became pregnant. Of 49 patients specifically complaining of sterility, treated in the past 10 years, 25 (51%) became pregnant. The relief of dysmenorrhea, pelvic pain, dyspareunia, and menometrorrhagia was gratifying. Six of the 200 patients have had secondary radical operations. The conservative operation for endometriosis requires care, tedious dissection, and often more time than hysterectomy. The results obtained confirm the impression that this operation is a satisfactory and proper method of treatment when it is strictly indicated because of disabling symptoms or because of sterility which does not respond to usual conservative procedures. It should not be performed though, until the patient has been observed and surgical intervention seems clearly necessary. In case of realization and necessity of a second laparotomy later, the conservative operation for endometriosis should not be considered a failure if normal health has intervened for a number of years or if pregnancy has occurred.

Delay by Physician and Patient in the Diagnosis and Treatment of Pelvic Cancer. C. E. Flowers Jr., R. A. Ross and N. L. Pritchett. South. M. J. **51**: 1497-1504 (Dec.) 1958 [Birmingham, Ala.].

According to the American Cancer Society, 50% of those who die of cancer could be saved if patients and physicians would familiarize themselves with and use all available knowledge of the disease. During a 4-month period 191 patients with pelvic cancer were studied at the North Carolina Memorial Hospital in Chapel Hill to determine the preventable factors in their disease. The charts of 70 of these patients who died of pelvic cancer were also reviewed. The incidence of delay on the part of the physician to give a proper diagnosis, and of delay on the part of the patient to consult a physician after the occurrence of the first symptoms of pelvic cancer, was established according to the Philadelphia Plan for Pelvic Cancer Control. It was evident that almost none of the patients had been advised by their physicians to have annual physical examinations. There were many patients who failed to report symptoms of pelvic cancer to their physicians, as well as an unfortunately large number of physicians who neglected to establish the diagnosis of pelvic cancer and to institute treatment. Delay in consulting a physician was found among 42% of the patients with carcinoma of the cervix, with an average delay period of 18 months. Delay in establishing a proper diagnosis was found among 19% of the physicians, and the average time elapsed between the patient's first visit to the physician and the establishment of the correct diagnosis was 9 months. Delay on the part of both patient and physician was found to be 14%, with an average delay period in consulting a physician and/or establishing a correct diagnosis of 14 months. Fifty-four per cent of the patients with invasive carcinoma of the cervic had no symptoms 6 to 12 months prior to consulting their physicians. Of the 46% who could have had their disease diagnosed before it became advanced, 16% delayed their visits to the physicians, and in 30% the physicians failed to make a proper diagnosis. Sixteen per cent of the patients with carcinoma of the endometrium delayed their visits to the physicians, and in 20% of these the physicians failed to make a correct diagnosis.

One cannot expect much improvement regarding delay in diagnosis and treatment until one impresses upon the public and the profession that in the majority of patients curable cancer is asymptomatic. The incidence of pelvic cancer can be materially reduced by physicians' stressing the importance of annual physical examinations and by the establishment of state and county committees for the study of pelvic cancer.

Cancer of the Cervix: Prevalence, Special Surgical Technique, and Evaluation of Results. S. Mitra. Cancer **11**:1190-1194 (Nov.-Dec.) 1958 [Philadelphia].

The anatomic distribution of cancer is not the same in different parts of the world. In a diagram the author shows the comparative incidence of cancer of different sites among patients in 2 institutions, the Cancer Hospital of Calcutta and the Royal Cancer Hospital of London. The preponderance of oral, laryngeal, and cervical cancer is marked in India. Cancer of the cervix constitutes 23.3% of all cancers in Indian women. This form of cancer was believed to be rare among Mohammedan women, but, in comparing the incidence of cervical cancer among Hindus and Mohammedans, the author found it to be practically the same. He believes that it is not the ethnological difference but the habits and the environment, the social status, and the assaults on the cervix from repeated childbirths that are responsible for the frequency of cancer of the cervix. There is no racial susceptibility to this type of cancer.

The author has been concerned with cancer of the cervix since 1924. During the early years of this period he treated all cervical cancers with irradiation therapy, as was then customary, but the first 5-year end-results were not encouraging, the cure rate being only 16.6%. Since then he has combined surgical with irradiation therapy. He resorted to Schauta's radical vaginal hysterectomy in preference to Wertheim's operation, because in India the primary mortality rate was much higher in Wertheim's than in Schauta's operation. There was only one ureteral fistula in a series of 391 patients operated on. Comparative 5-year end-results for patients with cervical cancer of stages 1 and 2 indicated better salvage with radical surgery (65.6%) than with irradiation therapy (43.5%). Postoperative complications were minimal with the author's technique of extraperitoneal lymphadenectomy and radical vaginal hysterectomy. Pelvic node metastases were found in 23.2% of the patients with cervical cancers in stages 1, 2, and 3 (38 of 164 in the newest series). The parametrium was rarely infiltrated; there was parametrial involvement in only 1 of 38 patients with metastases in the pelvic nodes.

The author concludes that the surgical method he employs in cervical cancer has definite advantages. This is substantiated by a 5-year salvage rate of 70% in patients with cervical cancers in stages 1, 2, and 3. Five-year survival has reached 84.6% for women in whom the pelvic nodes are not involved, compared with 43% for the group with metastatic cancer in the pelvic nodes.

***Twin Pregnancy in a Uterus Didelphys: A Case* Report.** W. M. Dawson and W. H. Ainslie. J. M. Soc. New Jersey **55**:649 (Dec.) 1958 [Trenton].

The authors present the history of a 22-year-old primigravida who was first seen on March 1, 1957. Her last menstrual period had been on Jan. 9, and her expected date of confinement was Oct. 16. Her antenatal course was uneventful until July 3, when palpation revealed the probable presence of a twin gestation and "double" uterus. There was a vertical midline groove on the uterus, giving an irregular "U" effect, with a distinct fetal heart in each limb of the "U." The patient went into labor spontaneously at 32 weeks of gestation. The first twin, a living male infant weighing 1417.5 Gm. (50 oz.), was delivered from the right uterus. The intact placenta was expressed spontaneously 5 minutes later.

At this time, the cervix of the left uterus was fully effaced and dilated to 4 cm., with bulging membranes which were ruptured artificially. Contractions continued irregularly and weakly in the left uterus. An infusion of oxytocin was begun with good results. and the second twin, a living male infant weighing 1615.9 Gm. (57 oz.), was delivered from the left uterus. The intact placenta was expressed 5 minutes later. Subsequent bleeding was minimal, and the patient's postpartum and puerperal course was uneventful. Both infants survived. The authors say that premature termination of pregnancy is usual in cases of double ovum twins, each twin residing in a separate half of a uterus didelphys, but the survival of such twins is extraordinary.

PEDIATRICS

Physiologic Abnormalities of Salicylate Intoxication. W. E. Segar and M. A. Holliday. New England J. Med. **259**:1191-1198 (Dec. 18) 1958 [Boston].

Forty-nine children were seen and treated for salicylate intoxication at the James Whitcomb Riley Hospital, Indianapolis, between 1952 and 1957. All were less than 6 years of age. Two were being treated for rheumatic fever. Of 43 with a history of salicylate ingestion, 11 children obtained the drug themselves or were fed it by an older sibling. The remaining 32 poisonings, primarily involving children under 2 years, were due to misguided therapeutic efforts of the parents, often upon the advice of a physician. There were 5 deaths, all in children less than 2 years of age; all 5 had severe hyperpyrexia. Eight children, of whom 6 were less than 2 years of age, had convulsions. The authors give particular attention to the metabolic alterations produced by salicylates. Hyperthermia, which is a prominent and occasionally a lethal result of salicylate intoxication, cannot develop unless the normal heat-regulating mechanisms are impaired. Since these mechanisms depend, in part, upon the evaporation of water from the skin and lungs, they are compromised by dehydration, which is observed in all children with serious salicylate intoxication. Both hyperventilation and sweating result in increased water and electrolyte expenditure. Vomiting and diarrhea occur frequently and contribute to the dehydration. Once the body water stores are depleted, salicylate can no longer induce effective sweating, and its hyperpyretic action is no longer balanced by effective defenses. Thus, hyperpyrexia accelerates dehydration, and dehydration potentiates hyperpyrexia. The greater loss of water than of electrolytes will result in hypernatremia.

Hyperglycemia occurred in 4 of the 14 children on whom appropriate studies were made. Salicylates have several separate pharmacological actions that alter carbohydrate metabolism. They increase "glucose demand," as well as the rate at which glucose is absorbed from the gastrointestinal tract; they probably increase the rate of production or of release of adrenal corticoids; and they interfere with the processes by which glucose is metabolized. Only the increase in glucose demand tends to lower blood sugar; the remaining 3 actions tend to produce hyperglycemia and glycosuria. The alterations in the carbohydrate metabolism also contribute to the production of ketosis. The urine of 30 children was examined for ketone bodies, and 27 of these tests were positive. Attention is called to the severe disturbances in the pH of the body fluids, including the early occurrence of a respiratory alkalosis, which is followed by a metabolic acidosis. The respiratory alkalosis is rarely of clinical importance except that it depletes the patient's buffering capacity and cation reserves for the acidosis that will follow. The various factors contributing to the metabolic acidosis, including abnormalities in carbohydrate metabolism and the production of ketosis, are reviewed.

Hyperthermia and dehydration are the immediate threats to life, and the initial therapy must be directed at their correction. External cooling with water or alcohol should be provided quickly to any child who has a rectal temperature over 104 F (40 C). Intravenous infusions of fluids must be prompt, because the patient's defense against hyperpyrexia can function only after the dehydration has been corrected. Electrolyte therapy, but not water, may be withheld until the presence of a metabolic acidosis can be confirmed and until the presence or absence of hypernatremia can be ascertained. Intravenous infusions of fluids similar to those that would be prescribed for a diabetic patient in acidosis should be planned for the succeeding 24-hour period. If the child is in shock or in impending shock, 20 to 30 ml. of Ringer's lactate solution per kilogram of body weight should be given rapidly before the 24-hour therapy is started. The initial fluids should contain no potassium. Other supportive measures may include the liberal parenteral administration of vitamin C and vitamin K.

A Controlled Study of Beta Hemolytic Streptococcal Infection in Rheumatic Families: I. Streptococcal Disease Among Healthy Siblings. J. M. Miller, S. L. Stancer and B. F. Massell. Am. J. Med. 25:825-844 (Dec.) 1958 [New York].

Data on the incidence of hemolytic streptococcic infections in 235 healthy children, between the ages of 5 and 16 years, who belonged to families that included at least one sibling with a definite history of rheumatic fever were collected from September, 1953, to June, 1956, at the House of the Good Samaritan, Children's Medical Center, Boston. Throat cultures and antistreptolysin O antibody levels served as the laboratory means of documenting all symptomatic streptococcic illnesses as well as asymptomatic streptococcic carrier states. Of 603 symptomatic respiratory illnesses occurring among the 235 children, 14% were associated with beta-hemolytic streptococci, and 90% of these organisms were of the group A variety. The most frequent clinical category of respiratory disease encountered was coryza which was rarely accompanied by laboratory evidence of streptococcic infection, whereas tonsillopharyngitis was the second most frequent clinical entity and showed a correlation with group A streptococci of 30%. Isolated fever was particularly associated with streptococci, and fever generally seemed to be the most important correlative finding of symptomatic streptococcic infection. Fully 55% of all group A hemolytic streptococcic infections observed were asymptomatic carrier states detected in children who were presumably well. Of the 603 symptomatic respiratory illnesses, 169 were group A hemolytic streptococcic infections. The diagnosis of group A hemolytic disease was made by positive culture in 157 (93%) of the 169, whereas immunological response alone was the basis for diagnosis in 12 (7%). Many different serologic types of group A organisms were detected among 151 isolations which were typed. Type 6 was most frequently encountered among the strains which could be typed. Of the 151 organisms studied, 53 (35%) could not be typed with the antiserums available. Suitable data on antistreptolysin O were available from 129 (76%) of the 169 group A hemolytic streptococcic infections observed, and a significant antibody rise was detected in 51 (40%) of the 129, of both symptomatic and asymptomatic groups of illnesses. The frequency of antibody response in the various categories of symptomatic streptococcic infection was about the same. Although the frequency of a significant antibody response seemed related to the numbers of streptococci in the throat, antibody rises occurred in the absence of positive throat culture in some cases. The 40% incidence of antibody response occurred in spite of early diagnosis and fairly prompt penicillin treatment of most such bacteriologically documented infections.

Three regimens of penicillin treatment were studied. An oral 10-day regimen of buffered penicillin G in a daily dose of 400,000 units was found to be suppressive for beta-hemolytic streptococci while the drug was administered, but bacteriological relapse occurred in 6 (30%) of 20 patients who received this treatment. A 10-day course of orally administered buffered penicillin G totalling 1.2 million units daily was highly effective in treating patients with symptomatic infections, was somewhat less effective in eradicating the carrier state, and was a failure in 9 (13.8%) of 65 patients so treated. A single intramuscular injection of 600,000 units of benzathine penicillin G failed in 4 (9.1%) of 44 patients. The oral program of treatment was well tolerated, with complete absence of side-effects of allergic reactions. The intramuscular preparation was tolerated with freedom from allergic reactions, but patients did complain of transient pain at the site of injection. Although no overt indication of typical rheumatic fever was seen after these 169 streptococcic infections, 2 instances of rheumatic heart disease appeared insidiously, and 1 instance of erythema marginatum was detected. The general occurrence rate of hemolytic streptococcic disease was greater among children of this study who still had their tonsils than among those whose tonsils had already been removed.

A Controlled Study of Beta Hemolytic Streptococcal Infection in Rheumatic Families: II. Penicillin Prophylaxis among Rheumatic Fever Subjects, Comparing Different Regimens. J. M. Miller, S. L. Stancer and B. F. Massell. Am. J. Med. 25:845-856 (Dec.) 1958 [New York].

The authors report on observations made during the period from 1953 to 1956 at the House of the Good Samaritan, Children's Medical Center, Boston, concerning the effectiveness of penicillin in the prevention of group A hemolytic streptococcic infections among children who were convalescing or who had completely recovered from acute rheumatic fever. A group of 452 hospitalized patients with acute rheumatic fever or a definite history of rheumatic fever received 200,000 units of buffered penicillin G given orally twice daily over the 3-year period. Another group of 114 rheumatic outpatients received 200,000 units of buffered penicillin G given orally twice daily, and 47 rheumatic outpatients received 1.2 million units of benzathine penicillin G intramuscularly at 4-week intervals. Healthy siblings of both outpatient groups of rheumatic children did not receive prophylactic penicillin and served as controls for measuring the incidence of streptococcic disease in these particular family environments.

No instances of recurrence of rheumatic fever developed among the entire group of 452 hospitalized patients, and in only 2 of these children did asymptomatic carrier states with group A streptococci develop. There was no case of elevation of antistreptolysin O among the entire group. There were 2 definite recurrences of rheumatic fever among the 114 rheumatic outpatients who received orally 200,000 units of buffered penicillin G twice daily, and there were no recurrences among the 47 rheumatic outpatients who were given 1.2 million units of benzathine penicillin G intramuscularly every 4 weeks. The oral regimen of prophylaxis achieved a striking reduction in streptococcic infections among the ambulatory outpatients receiving penicillin, as compared with their healthy siblings who were not so protected, and the intramuscular administration of long-acting penicillin showed even greater efficacy as a prophylactic agent. Among the 452 hospitalized rheumatic patients who received the continuous prophylactic amount of 200,000 units twice daily, there were only 3 with an untoward reaction of pruritic rash which required discontinuation of the penicillin preparation. None of the 114 outpatients showed adverse effects attributed to penicillin given orally. Subjective reactions among the patients who received penicillin intramuscularly were frequent. The reactions necessitated termination of this form of prophylaxis in 4 of these patients.

The results of this study have demonstrated the superior prophylactic benefit of repository injectable penicillin, but the risk of reactions has been greater than that associated with penicillin given orally. Oral therapy with penicillin is an effective agent in the prophylaxis of streptococcic disease, but continued cooperation by the patient is required in taking the drug by mouth. Both regimens have appropriate usefulness in the prevention of recurrences of rheumatic fever.

A Case of Cushing's Syndrome in an Infant. E. Goldblatt and A. H. Snaith. Arch. Dis. Childhood 33:540-542 (Dec.) 1958 [London].

The child presented was a girl, born after a normal pregnancy, who appeared normal when she was one year old. Two months later she was brought to hospital because of rapid gain in weight and increasing irritability. She was obese, with a buffalo hump, her face was plethoric, and she had an acneiform rash. There was slight hirsuties of the face and back. No striae were present. An intravenous pyelogram suggested enlargement of the right adrenal, and studies on the excretion of steroids revealed greatly increased values. In the expectation that an adrenal tumor would be found, an exploratory laparotomy was undertaken. Cortisone was given orally for 2 days prior to the operation. Both adrenals were found to be slightly enlarged and nodular. The left adrenal was removed, and after further investigation it was decided to remove the right adrenal. In preparation for the second adrenalectomy, cortisone was given orally and intramuscularly. The postoperative course was uneventful, the cortisone dosage was gradually reduced, and the patient was discharged 2 months later, by which time her appearance had become much more normal. At present she is on maintenance therapy with 20 mg. of cortisone acetate and 1 Gm. of salt a day. Three months after discharge the patient was again admitted to hospital, suffering from avulsion of 2 finger tips which had been caught in a train door. She withstood this trauma without any evidence of metabolic upset. The authors believe that this is the first time that adrenalectomy has been performed on an infant with adrenal cortical hyperfunction (Cushing's syndrome). The long-term prognosis remains to be seen.

Fourteen Personal Cases of Pneumocystis Carinii Pneumonia. G. Berdnikoff. Canad. M. A. J. 80:1-5 (Jan. 1) 1959 [Toronto].

The author reports on 7 male and 7 female infants with pneumonia due to Pneumocystis carinii, who were treated and who died at 4 hospitals in Canada between 1930 and 1958; the ages of the patients ranged from 2 to 4 months at the time of death. The clinical histories of the 3 most recent cases are summarized; these reflected rather faithfully the clinical aspect in all 14 patients whose lungs microscopically presented a typical picture of Pneumocystis pneumonia. Both sexes were equally affected. Four of the 14 infants were premature. Debility, whether due to prematurity or to other causes, seemed to be of major importance. The illness started with a sudden onset of periods of dry, unproductive cough accompanied by signs of suffocation. Cyanosis and polypnea were rather pronounced, and there was marked sternal retraction. Administration of oxygen usually brought relief, but symptoms recurred as soon as it was discontinued. There was no rise of temperature, except when the disease was complicated by another infection.

A symptom-free period of a few days' duration after the initial onset of the disease was definitely present in 7 of the 14 infants; it deserves special consideration, since it might become a valuable tool for the clinical diagnosis of the disease. The initial period of suffocation might be caused by edema and formation of hyaline pseudomembranes, which were well represented in certain regions of the lung of one of the patients, perhaps due to some hyperergic reaction. The disappearance of the exudate associated with pseudomembranes might then explain the remission of symptoms for a few days. This would be followed by new periods of suffocation, which now, however, were due to the direct obstruction of alveoli and bronchi by masses of the pullulating Pneumocystis organisms. Further observations are necessary in order to evaluate the exact incidence of the "symptom-free period."

Spontaneous pneumothorax was not rare among these patients. White blood cell counts varied between quite high values, up to 28,000 per cubic millimeter, and surprisingly low values, such as 8,900 per cubic millimeter, and for this reason cannot be depended on. The x-ray picture of the lung did not permit differentiation from other conditions, such as milk-aspiration pneumonia. There was absence of air usually in the perimediastinal regions of the lung parenchyma, accompanied by emphysema usually in the peripheral regions. The question of epidemiology still remains unanswered. Needle biopsy of the lung appears at present to be the only possible way of establishing a positive diagnosis during life. Nonfatal cases certainly exist, and it is left to the ability of clinicians to find a specific treatment.

Some Psychological Contributions to the Clinical Treatment of the Asthmatic Child. A. Macedo De Queiroz and A. Strauss. Acta allergol. 12:396-406 (no. 6) 1958 (In English) [Copenhagen].

The authors report on 40 children, between the ages of 2 and 11 years, with asthma who were admitted to the Hospital das Clínicas of the Medical School of the University of São Paulo, Brazil, and who were subjected to a specialized psychological study because of the close relationship between asthma and the personality of children. A clinical diagnosis of allergic asthma was the only factor in common of all the children in this group. They received medical treatment consisting of removal of specific allergenic factors and, when indicated, hyposensitization with allergenic extracts and autovaccines. Interviews were held with the patient and his relatives, and the patients were observed in free activities and were given psychological tests. The results of the psychological investigation revealed the existence of psychological factors directly related to asthma as causative agents, psychological factors indirectly related to asthma, and behavior problems frequently observed in children with asthma.

Direct influences included emotional tensions, resulting from conflicts at home, punishments, school examinations, parties, new situations such as entering school or playgrounds for the first time, and the feeling of being unwanted or having lost affection. The "use" of the asthmatic attack as a means to obtain specific ends, such as a mother's special care and attention, should also be considered as a factor directly influencing the disease. As indirect influences, there should be considered factors related to the emotional environment of the home, such as overanxious and depressive parents, marital conflicts, or unstable financial situations, and factors due to wrong educational attitudes, such as overprotection and constant vigilance over the asthmatic patient. Behavior problems accompanying the asthmatic symptoms included aggressiveness in 39 patients, anxiety in 32, overdependence on the mother or other family members in 28, anorexia in 23, fears in 23, negativism and stubbornness in 18, jealously, withdrawal tendencies, temper tantrums, and sleep disturbances in 13. These problems reflected clearly emotional and educational situations, as 34 of the 40 children had normal intelligence levels.

Combined psychological and medical-allergic treatment not only brought real benefit to the child's personality but also caused a more rapid improvement of asthma in all the children. Consequently psychological investigation seems absolutely justified. Psychopedagogic orientation to be given to the family is outlined. Psychological treatment, referring to the child's necessities and his psychological problems, was focused on enrichment of his experiences, canalization of aggressivity or elimination of its causes, elimination of causes of fear, support of achievements, and small tasks of responsibility at home. A specialized psychological examination would seem perfectly justifiable in patients with large psychological interference and when the family environment permits it.

Staphylococcic Pneumonia in Infants: Six Cases. E. Jaso and L. Abarca. Rev. españ. pediat. 14:663-676 (Sept.-Oct.) 1958 (In Spanish) [Saragossa, Spain].

Staphylococcic pneumonia is a severe and often fatal form of suppurative pneumonia which complicates some epidemics of influenza in infants. It is caused by Staphylococcus pyogenes var. aureus, which does not respond to treatment with sulfonamides, although it responds to chloramphenicol and to streptomycin. It may be complicated by (1) influenzal bronchitis, (2) a staphylococcic infection located at any distance from the respiratory tract, and (3) fibrosing pancreatitis. The early symptoms are those of pneumonia, with acute respiratory disorders: cough, dyspnea, fever, vomiting of hemorrhagic or purulent phlegm, and vascular shock. The roentgenograms of the chest are typical, showing innumerable pulmonary abscesses, both miliary and larger, up to 5 mm. in diameter. Most frequently the abscesses open into the pleura, causing empyema, pneumothorax, pyopneumothorax, or pneumatocele. Often there is a recurrence, with aggravation of the pneumonia.

Six cases of staphylococcic pneumonia in infants, between the ages of 1 month and 1 year, are reported. The predominant symptoms were typical of pneumonia in 4 cases and were similar to those of ileus in 1 and to those of pulmonary tuberculosis in 1. A diagnosis was made with certainty by the typical aspects of the lungs in roentgenograms of the chest, which showed unilateral pulmonary abscesses with pneumothorax or pneumatocele in 5 patients and bilateral pulmonary abscesses in 1. In all the patients there was polynuclear leukocytosis with intense nuclear deviation ("shift to the left"). Recovery was obtained through administration of erythromycin to 2 patients, of chloramphenicol to 2, and of streptomycin to 1. The patients with fibrosing pancreatitis and a pneumatocele died of recurrence of the pneumonia 4 months after the first attack.

Aminophylline Poisoning in Children. H. L. Bacal, K. Linegar, R. L. Denton and R. Gourdeau. Canad. M. A. J. 80:6-9 (Jan. 1) 1959 [Toronto].

The authors report on 10 children, between the ages of 8 months and 10 years, with aminophylline (theophylline ethylenediamine) poisoning arising from the therapeutic use of the drug in the management of bronchial asthma and upper respiratory infection. The drug was administered by the rectal route to 8 patients and intravenously to 1; in 1 patient the route of administration was not ascertained. The total known dosage ranged from 3¾ grains (225 mg.) for a 4½-year-old child to 22½ grains (1,350 mg.) in 36 hours for a 3½-year-old asthmatic child. Irritability, vomiting, hematemesis, and dehydration were nearly always present and complicated the preexisting disease for which the drug was administered. Albuminuria, drowsiness, convulsions, and cardiovascular syncope also were observed in some of the patients. Treatment of the intoxication was purely symptomatic, aimed at sedation, support of respiration and circulation, and prompt correction of dehydration. All the patients recovered and were discharged from the hospital within 24 hours to 14 days.

Theophylline is the most active of the xanthine agents, and the combination with ethylenediamine makes it more soluble and more completely absorbed. The xanthines stimulate the central nervous system, augment gastric secretions, cause diuresis, and exert central and peripheral actions on the cardiovascular system. The clinical manifestation of overdosage of aminophylline may be central nervous system stimulation with unusual restlessness and irritability; this is an early sign and may progress to tremors, epileptiform convulsions, drowsiness, and coma. Prolonged increase in gastric secretion may be manifested by nausea, persistent vomiting, or even hematemesis. Increased urine output may be associated with reversible albuminuria and dehydration. Cardiovascular collapse or even death may result. To eliminate preventable iatrogenic intoxication, the authors recommend the following dosages in the oral and rectal administration of aminophylline for the treatment of bronchial asthma in children: (1) suspension tablets given orally: 1½ grain (5 mg.) per kilogram of body weight; the dose may be repeated every 8 hours, but not oftener than every 6 hours; (2) rectal suppository or retention enema: ⅛ grain (7 mg.) per kilogram of body weight; the dose may be repeated every 8 hours, but not oftener than every 6 hours, and is to be restricted to patients in whom oral administration is not practicable. No undesirable side-effects were observed at the Montreal Children's Hospital with this regimen, which has been found adequate for treatment of children with asthma exclusive of those in status asthmaticus.

UROLOGY

Unilateral Multicystic Kidney: Report on One Case. G. Conca and E. De Nicolai. Minerva pediat. 10: 1097-1104 (Oct. 13) 1958 (In Italian) [Turin, Italy].

The authors report on a female infant with a unilateral multicystic kidney. At birth the child presented a mass which occupied the whole left flank; on the 5th day roentgenologic examination showed that the mass occupied the entire left side of the middle part of the abdomen and the uppermost part of the pelvis. The mass increased in size, and at the 8th month the child, who was otherwise in good condition, was operated on. A polycystic mass of the dimension of a small fetal head, occupying the whole left flank and part of the hypochondrium on the left, was isolated and enucleated. The mass substituted for the left kidney and showed some residue of parenchyma at the level of the hilus; the right kidney, the liver, and the pancreas showed no alteration. The mass was of a milk-white color and weighed 245 Gm. (9 oz.); its circumference was 21 cm. transversally and 26 cm. longitudinally. Structures identifiable as the vein and the artery of the kidney and a filamentous structure, a few centimeters long, without a lumen (probably an atresic ureter) were recognized. On section, the mass appeared to be composed of about 10 cystic formations of various dimensions and diameters. The cysts had a smooth surface and contained some clear watery liquid. The cystic cavities did not intercommunicate, and no excretory ducts were noticed macroscopically. Histological examination showed that the walls of the cysts were made up of connective tissue lined with cuboid epithelial cells. The tissue among the cystic cavities was made up of dense connective collagen. The child had a normal recovery, during which azotemia and urine tests gave normal values. Five months after the operation she was in good condition.

Evaluation of a Method for Detecting and Following Urinary Tract Infection in Females Without Catheterization. H. D. Riley Jr. J. Lab. & Clin. Med. 52:840-848 (Dec.) 1958 [St. Louis].

It is generally accepted that urine specimens for evaluation of urinary infection in women should be obtained by catheter, voided specimens being worthless because of contamination from the external genitalia. Yet there is evidence that bladder catheterization is not without danger of actually producing urinary tract infection. Patients immobilized by poliomyelitis and other paralytic diseases are particularly prone to infections of the urinary tract. A method of obtaining urine specimens for culture by a clean voiding technique without resort to catheterization was investigated in order to detect and follow the course of urinary infections in a group of paralyzed poliomyelitis patients. Subjects for this study included 34 female patients with paralytic poliomyelitis admitted to the Poliomyelitis Respiratory Center and 8 female patients with no clinical findings indicative of urinary tract infection admitted to other hospital divisions. Twenty-one of the poliomyelitis patients were over 15 years of age, and 13 were younger. Virtually all were immobilized and recumbent for long periods, and all except 2 experienced respiratory failure necessitating mechanical respiratory aids.

Urine for study was collected by the voiding technique. The first specimen passed by the patient in the morning was discarded. The second specimen was preferred. With the patient in the dorsal lithotomy position, the external genitalia were scrubbed thoroughly. Then the patient was encouraged to void, and the specimen was collected from the midportion of the urinary stream in a sterile container and immediately taken to the laboratory. It was either processed at once or stored in ice for not more than 3 hours. A catheterized specimen was obtained on the same day as the corresponding voided specimen, usually between 6 and 8 hours later.

Comparison of the paired samples collected from the poliomyelitis patients and from the controls according to the species and number of bacteria isolated revealed that satisfactory urine specimens for culture can be obtained by the voiding technique. When used in conjunction with colony counts or gram-stained smears of the urine, it is an adequate method of detecting significant bacteriuria in female patients. It is a valuable procedure for screening for urinary tract infection, especially in patients predisposed to urinary infection and in whom catheterization is almost certain to produce urinary infection. The risks inherent in bladder catheterization should not be neglected, and its use should be restricted to situations in which it is clearly indicated. To establish an accurate diagnosis of urinary tract infection, determination of the number of bacteria present in the urine is as important as their identification.

OTOLARYNGOLOGY

Carcinoma of the Larynx. G. E. Sheline and R. S. Stone. Ann. Otol. Rhin. & Laryng. 67:1066-1072 (Dec.) 1958 [St. Louis].

At a recent symposium on carcinoma of the larynx, sponsored by the American Cancer Society, it was evident that considerable disagreement exists in regard to the relative indications for surgery and radiation therapy. At the University of California Hospital in San Francisco a close cooperation has existed between members of the departments of otolaryngology and radiation therapy, which has resulted in a policy by which all carcinomas of the larynx are seen jointly by the staffs of the two departments. In general, radiation therapy was given preference in all cases in which there was a reasonable possibility that irradiation would control the lesion. The present review analyzes the results in 124 patients with histologically verified squamous-cell carcinoma arising in the endolaryngeal mucosa and treated by primary x-ray therapy during the period from July, 1942, through June, 1952.

Ninety-six of the patients had primary lesions of the vocal cord. Of these 96 lesions, 58 were controlled by radiation therapy alone; 2 radiation failures were controlled by secondary laryngectomy. Of the 30 patients with lesions which could have been treated by cordectomy, 24 received radiation therapy and were living and symptom-free at 5 years after treatment. Twenty nine of the 43 cord lesions which would have required total laryngectomy were controlled by irradiation alone. Five of the 19 patients with cord carcinoma, too advanced for control by laryngectomy, were salvaged by radiation therapy. Only 4 of the 26 supraglottic carcinomas were controlled by irradiation, but apparently none of the patients with these lesions would have been good candidates for surgery. Neither of the 2 subglottic carcinomas responded to irradiation.

Deafness Following Maternal Rubella: Results of a Prospective Investigation. A. D. M. Jackson and L. Fisch. Lancet 2:1241-1244 (Dec. 13) 1958 [London].

A national prospective inquiry into the effects of virus infections during pregnancy has recently been carried out by the Ministry of Health in Britain. During 1956-1957 a subsidiary investigation was undertaken on some of the children whose mothers had rubella during the first 18 weeks of pregnancy. The register of the national inquiry, which was compiled at the time of the mothers' pregnancy, included 79 surviving children from the counties of London and Middlesex whose mothers had rubella during the first 18 weeks of pregnancy. Fifty-seven of these children were still available for examination and constitute the rubella group. A control group, consisting of 57 children whose mothers had no infection during pregnancy, was also examined. The examination team consisted of a pediatrician, an otologist, an educational psychologist, and an audiology technician with experience in testing young children.

Reliable audiograms were obtained in all but 7 of the 114 children examined, and in these 7 the voice tests were considered adequate for the diagnosis of deafness to be confirmed or excluded. Fourteen of the 57 children whose mothers had had rubella during early gestation had congenital deafness. Such a diagnosis was made if the audiogram showed a hearing loss of 20 db. or more in at least 2 adjacent frequencies, or a loss of 30 db. or more in a single frequency. In 2 of the 7 children from whom reliable audiograms could not be obtained, a diagnosis of severe bilateral deafness was made on the results of other hearing tests. The remaining 5 children were considered to have normal hearing, but, in the absence of reliable audiograms, the possibility of minor degrees of hearing loss could not be excluded. In 5 of the 14 children the deafness was unilateral.

Since Gregg's original report on the effects of rubella during pregnancy in 1941, the early retrospective studies suggested that the incidence of congenital defect, including deafness, was very high. Later prospective investigations showed it as much lower. The authors believe that theirs is the first investigation to include detailed hearing tests with audiograms on a group of children from a prospective series. The group is to some extent selected, because it includes only live-born children from the national inquiry who survived to the age of 4 years and lived in the London area. The fact that 9 out of 14 cases of congenital deafness had not been detected by the age of 4 years indicates the importance of detailed hearing tests, including audiograms, in the diagnosis of deafness caused by rubella during gestation.

THERAPEUTICS

On the Use of Liver Extracts Regulating the Action of the Heart in Surgical Patients. C. Uggeri. Minerva med. 49:3928-3933 (Oct. 20) 1958 (In Italian) [Turin, Italy].

The author reports on his experience with Cortunon, an Italian proprietary liver-extract preparation which has a regulatory effect on the action of the heart. The extract was given to 174 surgical patients—to 83 before the operation and to 91 after the operation. The 83 patients who received the drug before the operation were given 3 intramuscular injections of 2 cc. per day for 2 to 4 days, followed by 2 injections per day, one in the morning and the other in the evening, for the remaining period preceding the operation, usually from 4 to 8 days. The treatment was resumed by mouth soon after the operation in half of these patients and was continued for a period of 5 to 10 days. Patients whose condition was serious received a beginning dose of 12 cc. per day, given in 3 injections, and a continuing dose of 6 to 8 cc. per day.

Liver-extract treatment in most of the patients was combined with analeptic or cardiotonic treatment and was well tolerated generally and locally. In 9 patients with exophthalmic goiter the drug was combined with other substances, such as iodine, sedatives, and vitamins. The heart condition of 6 of these patients improved within 2 to 4 days; their pulse rate diminished 20 to 35 beats per minute. In one patient the pulse rate which was 130 per minute was reduced to 80 per minute after 6 days of treatment with 6 cc. of Cortunon per day; the subjective symptoms disappeared. Three patients, who had been under medical treatment for several years but with poor results, derived no benefit from the liver-extract preparation until after a subtotal thyroidectomy. Poor results were obtained in 3 patients with essential hypertension, and there was no effect on the pulse rate of 4 patients with valvular lesions. Subjective symptoms, though, disappeared in 6 of 7 patients with coronary disease; in 1 patient with atrioventricular block and in 2 patients with early auricular fibrillation, the administration of Cortunon had a permanent beneficial effect.

Anticoagulants in Therapy of Arteriosclerosis. O. Castro Bianchino. Tórax 7:77-87 (March) 1958 (In Spanish) [Montevideo, Uruguay].

Eighty-three patients with arteriosclerosis were treated with anticoagulants during the past 3 years at the Puriel Semiologic Clinic in Montevideo. Before the treatment cholesterolemia was normal in 52 out of 66 patients and was increased in 14. The total lipids were normal in 35 out of 74 patients and were increased in 39. The lipidograms showed pathological tracings for 68 out of 83 patients and were normal for 15. The presence of hemorrhagic diseases and of diseases which are frequently complicated by hemorrhages was regarded as contraindication for anticoagulant treatment. Fourteen patients with myocardial or pulmonary infarction were treated with Tromexan (a coumarin derivative). The drug was given by mouth in an initial dosage which varied between 600 and 900 mg. divided into 2 or 3 fractional doses. The maintenance doses were regulated by the results of periodic determinations of the blood prothrombin time. Fourteen patients with cerebral or coronary arteriosclerosis or with arteriosclerosis of the legs had intravenous injections of a heparin solution, each injection containing 7,500 I. U. of the drug in 1.5 cc. The injections were given 3 times a week for 2 or 3 consecutive months. The remaining 55 patients were excluded from the study owing to their irregularity in reporting for consultation.

Either treatment was aimed at modifying the metabolism of lipids and the humoral changes which are responsible for pathological abnormalities in the wall of the arteries. Tromexan had no effect on the metabolism of lipids. Heparin, on the other hand, regulated the metabolism of *lipids* in the 14 patients to whom it was administered. The total lipids were increased in 10 patients, and the lipidogram tracings showed considerable improvement for 9. Great improvement from heparin treatment was obtained in 7 patients with anginal symptoms from coronary arteriosclerosis and in 4 patients with arteriopathy of the legs, with painful intermittent claudication. The satisfactory results have been maintained in all 11 patients for more than 3 months since discontinuation of the treatment. In the 3 patients with cerebral arteriosclerosis, though, the results of heparin treatment were mediocre. The tolerance of the 11 patients for heparin was perfect; none of them exhibited anaphylactic reactions. Since the treatment is expensive, it should be given only when (1) the lipidograms are characteristic of the disease, (2) there is a deficit in the amount of heparin in the blood, and (3) there are anginal symptoms or painful claudication of the legs.

Therapeutical Results as Obtained with Plasma Gamma Globulins of Human Origin: A Survey Covering 6,602 Cases: I. Main Indications for Their Use in Infectious Diseases. J. P. Soulier, M. Badillet and F. Herzog. Presse méd. 66:1881-1884 (Nov. 29) 1958 (In French) [Paris].

The authors give the results of a survey covering 6,602 cases of measles, whooping cough, rubella, mumps, smallpox vaccination complications, and smallpox, which were treated by the administration of plasma gamma globulins of human origin. The preparation was also used to prevent measles in 3,702 persons. The authors present results by groups in towns and in collectives. In the case of measles, injection of a solution of gamma globulins was generally practiced in the first half of the supposed incubation period of the disease. Complete protection against measles was provided for 878 persons out of 1,201 in the town group (73.2%). In 323 persons protection was not complete, and measles resulted, usually in an attenuated form; 125 of these patients had been exposed to prolonged contagion. In 3 of the failures titers of antibodies were insufficient, and in 19 of them the injection was given too late. Prophylaxis of measles in infants exposed to contagion was justified. The quality of attenuation was in direct proportion to the date of injection of the gamma globulin solution. In the group of collectives there were 3 categories: nurseries with healthy children; homes for children of different ages, frequently with physical weaknesses; and hospitals for sick children of different ages. A total of 2,501 children received injections; of this number 2,280 were completely protected against measles by the gamma globulin solution, but 182 had mild cases of the disease and 39 developed severe cases. Eighty-one patients who were given the preparation as a curative treatment of measles showed satisfactory results. In 12 patients measles was complicated by encephalitis, but 11 of them were completely cured.

Curative treatment of whooping cough with a solution of gamma globulins was beneficial for 150 patients treated at the Hospital for Sick Children in Paris. Therapeutic results were excellent in 144 patients, were average in 44, and were absent in 38. Preventive treatment of whooping cough resulted in complete protection of 360 persons out of 437 attempts. A survey of 349 patients was conducted essentially to define the preventive action of gamma globulin therapy on rubella in pregnant women and on congenital malformations in their children. Of 315 pregnant women, the majority of whom had been closely exposed to rubella, 312 were completely protected by the injection. The condition of the infant was described in 229 cases. Only one defect might possibly be attributed to rubella; this was a case of mental retardation, and it may not have been caused by the disease, because the exposure took place during the 6th month of pregnancy. Eight pregnant women with rubella received the gamma globulin solution curatively. The infant of one patient had not yet been born; the other pregnancies resulted in one miscarriage, one infant who died soon after birth, one infant with a light psychomotor retardation, and 4 normal children.

When the gamma globulin injections were used to prevent mumps, 92 out of 104 persons were completely protected, 10 contracted the mild form, and 2 developed severe cases. Thirty-six patients with mumps were treated with the preparation in an effort to shorten the course of the disease and to prevent complications. Results were good, particularly in orchitis parotidea which was cured in 3 or 4 days. Thirty-eight persons who had the gamma globulin treatment successfully escaped the complications of antismallpox vaccination. The therapeutic effect of these injections on 34 patients who developed such complications was good, with a rapid reduction in general signs and a fall in fever within a few hours. Sixty-eight persons who had been exposed to smallpox received the gamma globulin preparation, and all except 12 who had slight fever or benign smallpox escaped the disease. A cure with gamma globulin treatment was effected in one case of smallpox with complications.

Observations on Antibiotics in the Treatment of Hepatic Coma and on Factors Contributing to Prognosis. J. M. Stormont, J. E. Mackie and C. S. Davidson. New England J. Med. 259:1145-1150 (Dec. 11) 1958 [Boston].

The observation that urea-splitting bacteria in the colon were a significant factor in ammonia production and the demonstration of decreased portal-vein ammonia after the administration of antibiotics suggested that antibiotics should be of value in the treatment of hepatic coma. The combination of chlortetracycline with protein deprivation was shown to produce significant improvement in many patients with hepatic coma. Dietary protein has, however, been shown to be essential for adequate liver function in human subjects and animals. Neomycin administration to patients with chronic hepatic coma will allow additions of protein in amounts otherwise not tolerable. Since patients with cirrhosis may be in nitrogen balance with 30 to 50 Gm. of dietary protein, patients with hepatic coma at the Boston City Hospital have recently been treated with neomycin or paromomycin and protein withdrawal for 2 to 4 days; this was followed by administration of about 30 Gm. of dietary protein daily while antibiotics and other therapeutic measures were continued, the protein intake subsequently being increased as improvement occurred. In the last 2 years the authors studied 68 patients in hepatic coma or precoma. Sixty patients were considered to have cirrhosis of the alcoholic type, and 5 had "postnecrotic" cirrhosis, although a history of alcoholism was present in 2 of these. Two patients with hemochromatosis and one with metastatic carcinoma involving the liver were also included.

Seventy episodes of hepatic coma or impending coma were observed in the 68 patients, with recovery in 27 (39%). Twelve patients received chlortetracycline. Excluding these, there were 58 episodes in 56 patients, with recovery in 23 (40%) and improvement in 41 (71%), usually within 48 hours; of these 58 episodes, the patients in 34 were treated with paromomycin, resulting in 14 recoveries (41%), and in 24 with neomycin, resulting in 9 recoveries (38%). Thus, there was essentially no difference among the various antibiotics used in conjunction with readministration of protein. Comparison with 35 patients treated with complete protein withdrawal and chlortetracycline in the same hospital during the previous year also revealed no important difference in improvement and recovery. The majority of fatalities were related to potentially correctable complications, such as hemorrhage and infection. Liver failure was also an important cause of death, and prognosis was adversely affected by elevated serum bilirubin or electrolyte abnormalities. No evidence of neomycin or paromomycin toxicity was encountered, and severe diarrhea was not a problem with the doses used in this regimen.

Production of Impending Hepatic Coma by Chlorothiazide and Its Prevention by Antibiotics. J. E. Mackie, J. M. Stormont, R. M. Hollister and C. S. Davidson. New England J. Med. 259:1151-1156 (Dec. 11) 1958 [Boston].

Development of impending hepatic coma, characterized by confusion, drowsiness, and flapping tremor, has been described previously in patients with cirrhosis given nitrogenous substances by mouth—ammonium cation-exchange resins, ammonium salts, urea, methionine, and increments in dietary protein. It has also been reported in patients given a carbonic anhydrase inhibitor, acetazolamide. The authors here report the production of impending hepatic coma in alcoholic patients with cirrhosis and ascites given chlorothiazide, a nonmercurial diuretic agent. Chlorothiazide, administered to 5 alcoholic patients with cirrhosis and ascites, was observed to produce impending hepatic coma in 3 of these patients. This was associated with increased arterial ammonia concentration, increased sodium and potassium excretion, and a fall in serum potassium concentration. Impending hepatic coma was prevented by the concurrent administration of broad-spectrum, nonabsorbable antibiotics, and the oral administration of potassium chloride supplements prevented hypokalemia. The authors conclude that chlorothiazide is a useful diuretic agent in some patients with cirrhosis and ascites, but these patients must be carefully observed for the development of impending hepatic coma and hypokalemia. Potassium chloride supplements may be necessary.

PATHOLOGY

Malignant Cells in Peripheral Blood. J. C. Pruitt, A. W. Hillberg and R. F. Kaiser. New England J. Med. 259:1161-1164 (Dec. 11) 1958 [Boston].

This report is concerned with the study of results obtained by the use of a new method by which it is possible to examine quantitatively up to 20 ml. of peripheral blood for the presence of malignant tumor cells. In cooperation with the health office of Washington County, Maryland, and the private physicians of Hagerstown, Md., 20-ml. specimens of peripheral blood were obtained from a vein in the antecubital fossa of patients with and without cancer. The usual technique of venipuncture was used, but the syringe contained approximately 50 mg. of Lipo-Hepin to prevent coagulation. The blood was collected in sterile tubes and refrigerated for brief periods, permitting transport to the central laboratory.

The procedure for processing the blood was that described by Malmgren and associates (*J. Nat. Cancer Inst.* 20:1203, 1958). The procedure involves the addition of streptolysin O as hemolysin and leukocidin followed by passage of the resultant material through Millipore filters. Five or six filters are required for each specimen. The filters are removed after filtration from the special funnel apparatus and stained by the Papanicolaou technique. After staining, each entire filter is mounted on a glass slide and permanently sealed with permount and a cover slip. The slides are then ready for microscopic examination. Three hundred blood specimens, obtained from 100 patients with cancer and from 200 presumably well people, were studied. Examination revealed that cytologically malignant cells were identifiable in 39% of patients with cancer, and suspicious cells were present in an additional 12%. In the control group of 200 persons, cells that were considered to be cytologically malignant were found in only one (or 0.5%).

It seems likely that malignant squamous cells exfoliate into the blood at least as often as cells from adenocarcinomas. Sarcomas exfoliate cells into the blood with about the same regularity as carcinomas. Melanoma cells were found in the peripheral blood of 2 patients out of the 3 examined. These melanomas were not advanced, and the patient whose specimen was negative had been treated by total excisional biopsy 3 days before the specimen was obtained. It seems that one has about the same chance of identifying malignant cells in the peripheral blood in patients whose disease is local only but no treatment has yet been instituted as in patients whose disease has spread from its site of origin but treatment has been obtained. The reasons for this are not entirely clear, except that most often the spread of the lesion is to the lymph nodes, and these nodes may act as filters. A statistically significant analysis of the relation of the site of origin of the tumor to the presence of malignant cells in the peripheral blood proved impossible, but the biological activity of the tumor seems to be of importance. Malignant cells are not present in enough volume to justify examination of peripheral blood to make a primary diagnosis of cancer except in suspected cases that have eluded diagnosis by other means. Further evaluation of the method is required. It may be of value to follow patients after operation to indicate the presence of unsuspected metastases.

Analysis of Lipids of the Arterial Wall. C. J. F. Böttcher, J. G. Keppler, C. C. ter Haar Romeny-Wachter and others. Lancet 2:1207-1209 (Dec. 6) 1958 [London].

The authors carried out a detailed analysis of the lipids extracted from 22 single human aortas in different stages of atherosclerosis, which were obtained from autopsies performed at the laboratory of pathological anatomy of the University Hospital in Leiden, The Netherlands. Phospholipids, free fatty acids, sterol esters, glycerol esters, and free sterols were extracted from these aortas. The composition of the fatty acid mixtures from 4 of these 5 fractions were analyzed by gas chromatography. The results of these studies did not confirm the hypothesis that the deposition of saturated cholesterol esters is a characteristic feature of atherosclerosis. On the contrary, the proportion of saturated sterol esters fell as the severity of atherosclerosis increased, as also did the proportion of saturated phospholipids. The degree of saturation of triglycerides bore little relation to the degree of atherosclerosis. The authors decided to continue their analyses, paying special attention to the ratio between nonessential and essential unsaturated fatty acids deposited in the aorta, and a more detailed account will be published soon.

Experimental Production of Carcinoma with Tobacco Products: V. Carcinoma Induction in Mice with Cigar, Pipe, and All-Tobacco Cigarette Tar. A. B. Croninger, E. A. Graham and E. L. Wynder. Cancer Res. 18:1263-1271 (Dec.) 1958 [Chicago].

The authors previously published results of the experimental production of carcinoma of the skin in mice after application of cigarette tar condensate in 3 strains of mice, as well as in rabbits. The present study is concerned with comparing the biological activity of different types of tobacco products, such as cigars, pipes, and all-tobacco cigarettes. The smoking machine and the manner in which cigarettes were smoked and tars prepared for use were described in previous publications. A popular brand of cigars was puffed 3 times a minute, pulling a 50-ml. puff over a period of 4 seconds. This increase in volume and length of puff was necessary to keep the cigars lit and to give an adequate draw. The smoking time averaged 26 minutes. All-tobacco cigarettes were prepared by wrapping cigarette tobacco in tobacco leaf. These special cigarettes were smoked under the same conditions as standard cigarettes, but, owing to the waxy tobacco outer wrapping, they were smoked more slowly than the latter, averaging 16½ minutes per cigarette.

The most important finding of this study is that all types of tobacco smoke condensate tested have substantial carcinogenic activity. This observation is in line with human epidemiologic data which show a relationship between all types of tobacco smoke and cancer of the respiratory tract, that of cigarettes mainly for the lung and that of cigars and pipes primarily for the oral cavity. The highest percentage of both papillomas and cancers was found in the group of Swiss mice painted with nicotine-free pipe and cigar tars. This indicates a somewhat higher degree of carcinogenic activity for cigar and pipe tars than for cigarette tar and a somewhat less activity for all-tobacco cigarette tar compared with standard cigarette tar. Some of the differences could be a result of differences in biological variation. A comparison of whole tobacco tar with diluted tobacco tar suggests that dilution of tar accelerates tumor formation, apparently as a consequence of increased absorption of tobacco carcinogens. A comparison of the carcinogenic activity of freshly prepared tar with that of "old" cigarette tar showed no differences in activity. Present data reemphasize the viewpoint that tobacco carcinogens are formed during the process of combustion of tobacco and that the amount of tobacco carcinogens formed depends on the temperature reached and the completeness with which the combustion process occurs. Preventive measures directed toward reducing tobacco carcinogens must apply to all tobacco products.

Observations on Aberrant Renal Arteries Curving Around and Compressing the Renal Vein: Possible Relationship to Orthostatic Proteinuria and to Orthostatic Hypertension. H. Nathan. Circulation 18:1131-1134 (Dec.) 1958 [New York].

On the dissection of 400 renal pedicles obtained from 200 dissecting-room cadavers in Philadelphia and Jerusalem, the author found in 7 cases (3.5%) an aberrant inferior polar renal artery, curving around the normal renal vein. Six of these aberrant vessels were on the left side, and one on the right. The polar renal artery originated from the aorta below the level of the corresponding renal vein, and proceeded upward and laterally behind the vein. At the upper border of the vein, the artery curved downward and descended in front of the vein, to reach the kidney near its lower pole. The artery thus described an arch over the renal vein. In all instances the artery was intimately related to the renal vein, which appeared constricted and angulated under the arch of the artery. This kind of aberrant artery could be the cause of compression of the renal vein, particularly in the erect posture. The possible consequences of such compression are discussed with special reference to orthostatic proteinuria. The possibility also is considered of the aberrant artery being partially compressed by the renal vein, again particularly in the erect posture. Should this occur, an "intermittent Goldblatt mechanism" might be established, which would offer an explanation for the causation of some cases of orthostatic or postural hypertension described in the literature.

BIOCHEMISTRY

Critical Evaluation of the Precipitation Test for Systemic Lupus Erythematosus. L. E. Böttiger. J. Lab. & Clin. Med. 52:909-911 (Dec.) 1958 [St. Louis].

The precipitation test with which Böttiger is concerned was described by Jones and Thompson in The Journal, March 22, 1958, page 1424. The test is carried out by adding a 12% solution of *p*-toluenesulfonic acid in glacial acetic acid to serum. The authors claimed the test to be specific for systemic lupus erythematosus and stated that they had found very few false positives. These false-positive reactions were found in cases of hepatitis, in disseminated coccidioidomycosis, and in 2 cases of fulminating multiple myeloma. It is well known that an increase of the gamma globulin fraction in the serum is often found in systemic lupus erythematosus. This also is the case in diseases that give false-positive reaction. To test the hypothesis that the precipitation test is a nonspecific reaction, 158 serum samples were examined. All had been sent to the department of clinical biochemistry for various routine analyses from different departments of the Karolinska Hospital in Stockholm. Results of the examination of the 158 serums seemed to indicate that the test was not specific for systemic lupus erythematosus but dependent on the gamma globulin content of the serum.

Absorption of Vitamin B_{12} in Pernicious Anemia: Defective Absorption Induced by Prolonged Oral Treatment. M. Schwartz, P. Lous and E. Meulengracht. Lancet 2:1200-1204 (Dec. 6) 1958 [London].

The authors studied vitamin B_{12} absorption in patients with pernicious anemia, both treated and untreated. Without intrinsic factor the urinary excretion of radiocobalt (Co^{60}) vitamin B_{12} in 17 untreated patients with pernicious anemia varied between zero and 4.4% as compared with normal values varying between 10 and 40%. When Co^{60} vitamin B_{12} was administered together with 100 mg. of hog pyloric mucosa, the excretion in all the patients attained normal levels, with values ranging from 12.4 to 29.5%. All these patients with untreated pernicious anemia had some, although very slight, spontaneous intrinsic factor activity, the average excretion being 2.2% without supplementary intrinsic factor. Sixteen patients with pernicious anemia treated solely with new preparations of vitamin B_{12} combined with hog pyloric mucosa, administered orally for periods varying from 3 months to 4 years, were examined in the same manner without intrinsic factor and with 100 mg. of hog pyloric mucosa. Only 5 patients showed a normal absorption of vitamin B_{12}, and the remaining 11 showed blockage of absorption of vitamin B_{12}. Vitamin B_{12} absorption tests also were performed on 10 patients with pernicious anemia treated solely with the old-type preparations of crude stomach (pylorus) for several years. Of the 10 patients, 2 showed subnormal absorption values with 100 mg. of hog pyloric mucosa; but these patients, despite the extremely long period of therapy, absorbed vitamin B_{12} excellently, in sharp contrast to patients treated with combination preparations for quite brief periods. Most of the patients who have had pernicious anemia for a long time have lost the last spontaneous intrinsic factor activity, the average excretion of vitamin B_{12} without supplied intrinsic factor being 0.6%, as compared with 2.2% in the untreated patients.

The blockage of absorption of vitamin B_{12} caused by oral treatment of pernicious anemia with combined preparations of vitamin B_{12} and hog pyloric mucosa, demonstrated previously, was confirmed. Such blockage is very common, and it often occurs after treatment for a few months. Patients treated with preparations of crude pylorus either develop this blockage not at all or to a negligible extent. The blockage is related to hog pyloric mucosa. Vitamin B_{12} bound to this substance is poorly absorbed despite the presence of active human intrinsic factor. Alterations in the intestinal flora do not appear to explain the blockage. The blockage is not present in absorption tests with homologous intrinsic factor or with intrinsic factor from another species (rat). This observation supports significantly the hypothesis that blockage is an immunity phenomenon, the intrinsic factor being to some extent species-specific.

PUBLIC HEALTH

Effectiveness of Influenza Vaccines During an Epidemic of Asian Influenza. B. F. Gundelfinger, W. T. Stille and J. A. Bell. New England J. Med. 259:1005-1009 (Nov. 20) 1958 [Boston].

An epidemic of respiratory illness, associated with Asian influenza, occurred in the early fall of 1957 at the United States Naval Training Center, Great Lakes, Ill. Of 3,355 Navy recruits who arrived at Great Lakes between Aug. 7 and Sept. 18, 1957, about 30% were given a 1-cc. subcutaneous inoculation of monovalent influenza-virus vaccine (A/Japan/305-57) reported by the manufacturer to contain 200 chick-cell-agglutinating (CCA) units per cubic centimeter (vaccine A). Another group (about 30%) were given a 1-cc. subcutaneous inoculation of polyvalent influenza vaccine containing 250 CCA units, each of Formalin-inactivated A/Swine, A'/FM1, and B/GL/1739-54 viruses (vaccine B). The remainder of the recruits (about 40%) were given an inoculation of either a trivalent adenovirus vaccine or a placebo inoculation and served as controls. Of 964 recruits in whom febrile respiratory disease occurred during the study period from Aug. 25 to Nov. 9, 1957, 152 were inoculated with vaccine A, 299 received vaccine B, and 513 were in the control group. This gives an attack rate of 23.5 per 1,000 per week in the vaccine A group, 49.7 per 1,000 per week in the vaccine B group, and 58.9 per 1,000 per week in the control group. During the epidemic an 83 to 90% reduction in febrile respiratory illness was associated with prior inoculation with a monovalent Asian-influenza vaccine containing only 200 CCA units of A/Japan/305-57-strain virus. A similar 21 to 46% reduction was associated with prior inoculation with the polyvalent influenza vaccine not containing the Asian strain. Although a marked protective effect was noted as early as 10 days after inoculation, a slight beneficial result was noted before that time. No untoward reactions to the vaccine were observed. It is concluded that the Asian influenza vaccine was highly efficacious under the conditions of use at Great Lakes in the fall season of 1957.

Effect of Eradicating Brucellosis in Cattle on Incidence of Human Cases. J. R. Held, H. Bauer and R. L. West. Pub. Health. Rep. 73:1096-1100 (Dec.) 1958 [Washington, D. C.].

Brucellosis was first reported in humans in Minnesota in 1927, and there was a general trend toward an increasing number of cases until 1946. Since 1946 the trend has been downward, for whereas the case rate per 100,000 population was 13.84 in 1946, it was 1.94 in 1956. An awareness of the presence of brucellosis in the state was needed before the majority of cases could be diagnosed. In 1927 serologic and bacteriological services were introduced into the laboratories of the Minnesota Department of Health to aid in the diagnosis of brucellosis. These services have been used increasingly by practicing physicians since that time. The only cases counted by the Minnesota Department of Health are those confirmed by an agglutination test with a titer of at least 1:80, accompanied by clinical symptoms suggestive of brucellosis, or confirmed by isolation of the Brucella organisms from blood cultures.

This paper is particularly concerned with the effect of the area certification program on the number of human cases of brucellosis. In 1939 the Minnesota Legislature enacted a law authorizing the State Livestock Sanitary Board to control and eradicate brucellosis in cattle by means of an area plan. Under this plan all cattle owners in a specified area are required to participate in a testing program. The law also provides for the slaughter or isolation of all cattle reacting to tests and regulates the importation of any cattle into the area according to whether the animals, or herds from which they originate, are infected or not. By 1956 all the counties in the state were operating under this plan. Coincident with progress in the eradication of brucellosis in cattle, there has been a significant reduction in the number of human cases. Since 1940, when the first counties were certified, the case rate has been 3.12 times greater in noncertified than in certified counties.

Other factors undoubtedly affecting the number of human cases of brucellosis in Minnesota are the number of cattle in the state. From 1927 to 1948, when the number of cattle increased or decreased, there was a corresponding increase or decrease in the number of human cases of brucellosis. But from 1950 to 1956 the number of human cases declined markedly in spite of a high increase in the cattle population. This change in trend results from the elimination of some sources of human infection by the acceleration of the program of eradicating the disease in cattle.

BOOK REVIEWS

The ABO Blood Groups: Comprehensive Tables and Maps of World Distribution. By A. E. Mourant, M.A., D.Phil., D.M., Director, Medical Research Council Blood Group Reference Laboratory, Lister Institute of Preventive Medicine, London, Ada C. Kopeć, D.és Sc., Statistician, Nuffield Blood Group Centre, London, and Kazimiera Domaniewska-Sobczak, M.A., A.L.A., Librarian, Nuffield Blood Group Centre. Occasional publication no. 13 of Royal Anthropological Institute. Cloth. $8.50. Pp. 276, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada. 1958.

The authors of the monograph have made a useful contribution to physical anthropology by compiling and tabulating the results of the studies on the distribution of the A-B-O groups and the subgroups of A throughout the world. For all large populations, moreover, the frequencies of the blood group genes have been calculated and tabulated. A debt of gratitude is due the authors for having undertaken the Herculean task of culling the vast literature, classifying the data, computing gene frequencies, and publishing all this information in a single volume.

Recent Advances in Pædiatrics. Edited by Douglas Gairdner, M.A., D.M., F.R.C.P., Pædiatrician to Addenbrooke's Hospital, Cambridge. Second edition. Cloth. $9.50. Pp. 378, with 82 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W. 1, England.

This edition follows its predecessor by four years with a compendium of 13 articles covering those pediatric fields in which it is considered that significant progress in understanding or treatment has recently been made. The contributing authors are English with the exception of three American writers of two chapters. The following subjects are covered: changes in circulation at birth and the effects of anoxia, hematology of infancy, jaundice in the newborn, physical growth, hypothyroidism, spina bifida cystica, hydrocephalus of infancy, the nephrotic syndrome, tuberculosis, rheumatic fever, the deaf child, and pyogenic osteitis. Each of these small monographs gives either a complete résumé of the present investigational or therapeutic understanding in its field or a survey of newer approaches made, as in the case of childhood deafness. The chapters on hematology, jaundice of the newborn, and rheumatic fever are the most extensive and are full of practical, useful information. The section on tuberculosis is informative as to the control of this disease and the influence of the newer drugs and hormones on its course. Some of the articles are based primarily on the author's experience while others quote extensively from the current literature. Every chapter has a good up-to-date bibliography. Thus each section provides an excellent orientation and survey of a field of pediatrics in which significant progress in treatment or knowledge has been made. The British concepts do not differ from those held in the United States. This book is recommended as a better than usual source of information on its 13 subjects for any physician concerned with these problems in children.

Streptomycin and Dihydrostreptomycin. By Louis Weinstein, Ph.D., M.D., Professor of Medicine, Tufts University School of Medicine, Boston, and N. Joel Ehrenkranz, M.D., Assistant Professor of Medicine, University of Miami School of Medicine, Coral Gables, Florida. Foreword by Chester S. Keefer, M.D. Antibiotics monographs no. 10. Under editorial direction of Henry Welch, Ph.D. and Félix Martí-Ibáñez, M.D. Cloth. $4. Pp. 116, with 13 illustrations. Medical Encyclopedia, Inc., 30 E. 60th St., New York 22. Distributors outside U. S. A.: Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

This book provides a clear and reasonably complete exposition of the history, properties, methods of susceptibility-testing and assay, bacterial resistance and synergism with other antimicrobials, pharmacology, untoward reactions, and uses in various types of clinical infections, including application in combination with other antibiotics, of streptomycin and dihydrostreptomycin. A brief final chapter describes the use of streptomycin in the isolation and culture of viruses. Although the authors have not attempted to review all previously reported studies, the book takes into account most of the important published papers on the streptomycins. It is unfortunate that no reference was made to the study reported by Wier and co-workers (*Dis. Chest* 30:628-632 [Dec.] 1956) which revealed that, from the standpoint of hearing impairment only, therapy with the combination of streptomycin-dihydrostreptomycin (Streptoduocin) may be more hazardous than with streptomycin alone. The bibliography provided is extensive and is annotated in the text. A subject index included at the end appears to be carefully compiled. This book should be welcomed by all clinicians as well as laboratory investigators who have a special interest in antibiotics.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUESTIONS AND ANSWERS

WEIGHT GAIN AFTER CESSATION OF SMOKING

To the Editor:—*Many persons who stop smoking quickly gain weight. In most of them this is undoubtedly due to an improved appetite with consequent increase in caloric consumption, but some who have "kicked the habit" stoutly maintain that they are gaining weight in spite of the fact that they have not increased either food or beverage consumption. Is there any metabolic change that might account for some of this weight gain?*

John Trapnell, M.D., Philadelphia.

Answer.—Weight gain after cessation of smoking, just as true weight gain under any circumstances, must be due to an excess of calorie intake over calorie expenditure. The insidious increase of calories is effected by two significant factors. Smoking may inhibit gastric motility for 15 to 60 minutes; consequently, in most chronic smokers hunger and appetite are depressed. Psychic restlessness, previously satisfied by smoking, is now appeased by the substitution of food. As in most obese persons, minor nibbling and between-meal snacks may add up to an astonishing number of calories. The pharmacological effects of nicotine are complex. An immediate stimulating action on the autonomic nervous system, the adrenal medulla, and vasomotor cortex occurs, which results in an increase in heart rate, cardiac output, and respiratory rate and elevation in blood pressure. These may, in turn, cause acceleration of metabolic processes, but this initial action is followed by depression of the same systems so that one must assume that the effect is the summation of these two phases. It must therefore be concluded that little alteration in metabolic processes occurs after cessation of smoking.

SKIN DIVING AND POLYCYTHEMIA VERA

To the Editor:—*Is there a relationship between skin diving and true polycythemia vera? In a 35-year-old man with a hemoglobin level of 21 Gm.%, should further diving be restricted?*

Richard O. Bagley, M.D., Richmond, Calif.

Answer.—Some distinction might be made between scuba diving (self-contained underwater breathing apparatus) and snorkel diving. The former does not involve breath-holding, but the latter does to some extent. Snorkel diving might therefore be expected to induce an adaptive polycythemia and intensify symptoms, if any, of an already existing polycythemia. This is purely theoretical, however, for no case has been reported of an adaptation of this sort or any deaths or sickness in skin divers with symptoms (thrombosis or hemorrhage) suggesting polycythemia as a contributory cause. There is no record of actual experience that would justify restricting this man's activities in this direction. A remarkable article by Auerback and associates (*Pediatrics* 21:54, 1958) includes mention of a 12-year-old boy who had hemoglobin levels as high as 24 Gm.% with no symptoms other than "pink-eye." These authors believed that the presence or absence of troublesome symptoms should determine whether anything should be done in the way of limiting activities or starting treatment.

MONGOLISM

To the Editor:—*An article in a Spanish medical journal discussed the treatment of Mongolism with androgens, with favorable results. Is dehydroepiandrosterone available in the United States? Please comment also on powdered calf pituitary extract in the treatment of Mongolism.*

O. L. Frank, M.D., Maquoketa, Iowa.

Answer.—Hormonal treatment of Mongolism was first advocated in the United States several years ago. The regimen advocated consisted of the oral administration of pituitary substance from the immature animal (calf), on the premise that the pituitary of the immature and adult animal differ in growth-stimulating ability, plus thyroid substance as a mordant. Several aspects of this treatment may be viewed with concern. The cause of Mongolism remains unknown. Although histological changes in the pituitaries and thyroids of affected persons have been demonstrated, there is as yet no evidence for hypofunction of these or any other endocrine systems in Mongolism per se. Several studies have shown normal thyroid function in patients with Mongolism. Bovine growth hormone has not proved effective in the treatment of growth failure in man. Animal studies have demonstrated no difference in the growth-stimulating ability of the immature and adult pituitary, and growth hormone is not effective by the oral route. Reports of this form of therapy have not shown significant improvement in Mongolism. Clin-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ical and biochemical evidence of hypothyroidism has been noted in some such persons and evidence of hyperthyroidism in a very few. Here, appropriate therapy may be directed toward the thyroid disturbance, but it leaves the Mongoloid state unchanged. There is no evidence of androgen deficiency in persons with Mongolism and, therefore, no rationale for its administration. There are no known indications for the clinical use of dehydroepiandrosterone. It is commercially available in the United States for laboratory use.

METHANE IN WATER SUPPLY

To THE EDITOR:—*A newly driven well, 380 ft. deep, emits what appears to be natural gas. Does this admixture of gas render the water hazardous for household use? Should the water be submitted for chemical analysis and, if so, to whom?*

Charles H. Kosmaler, M.D., Elmira, N. Y.

ANSWER.—If the gas is methane, as it probably is, the water is dangerous to use because of the explosion hazard. A method of collecting and analyzing water samples for methane is given by Buswell and Larson (*J. Am. Water Works A.* 29:1978, 1937). The state or local health department can give advice on this problem. Carbon dioxide is a more common gas in ground waters. Since carbon dioxide is removed by passage through lime water or sodium hydroxide, a qualitative test can be done to determine whether the gas in question is carbon dioxide.

CHRONIC OTITIS MEDIA

To THE EDITOR:—*A 15-year-old boy has had chronic otitis media for several years. The drainage is purulent and often sanguineous. Examination revealed an old perforation, now barely visible, with chronic inflammation and drainage over the canal and drum. Roentgenograms taken in July, 1957, and October, 1958, showed no change, no cholesteatoma, and apparently normal mastoids. Culture revealed Staphylococcus pyogenes var. aureus sensitive to chloramphenicol, streptomycin, nitrofurazone, neomycin, and erythromycin. Chloramphenicol by mouth and in ear drops was tried for one week with little change. Cortisone had been tried previously with transient success and later with no success. What treatment should be used?* *M.D., Washington.*

ANSWER.—This is a chronic suppurative otitis media. The information furnished is not sufficient for a specific answer. Regarding the roentgenograms, which were said to show no cholesteatoma and apparently normal mastoids, such films frequently do not give definitive information. Cholesteatoma in the attic, for example, may not show up on a roentgenogram except in special films which have been carefully made. The culture in a chronic condition is frequently not significant, since it varies from time to time. The most essential information needed to understand the pathological process in this case is the finding on otoscopic examination. For example, a perforation in the pars flaccida of the tympanic membrane or along the upper periphery of the drum has quite a different significance from a central perforation in the membrane proper. A history that includes such factors as recurring upper respiratory infections, allergic episodes, and obstruction to nasal breathing is significant. Without such information it is not possible to give an intelligent opinion as to how such a condition should be treated.

TRIPLE VACCINE

To THE EDITOR:—*Is triple vaccine (pertussis, tetanus, and diphtheria antigens) to be preferred to double vaccine (tetanus and diphtheria only) when immunizing children of grade school age?*

C. W. Truesdale, M.D., Glencoe, Minn.

ANSWER.—There should be no doubt that it is preferable to give the triple antigens rather than tetanus and diphtheria alone when conducting a campaign of primary immunizations. The pertussis vaccine might be omitted if a child was known to have had whooping cough. Pertussis can be a serious disease in young children as well as in infants.

COMPOSITION OF HYDROCELE FLUID

To THE EDITOR:—*Have any studies been made on the enzymatic activity (lipase, esterase, acetyl choline esterase, and blood amylase) of hydrocele fluid? Not infrequently, one sees calcific plaques in the hydrocele sac containing large amounts of cholesterol. Have any determinations of the cholesterol content of hydrocele fluid been made?* *Ralph R. Landes, M.D., Danville, Va.*

ANSWER.—Hydrocele fluid in infants and children is derived from the peritoneal cavity through a hernial sac. In adults, particularly in elderly men, such fluid may represent an exudate from neighboring structures and possibly be associated with some inflammatory processes. This may also be the case with encysted hydroceles in the neck of the scrotum along the route of the original peritoneal evagination. Available information on the chemical constituents of peritoneal fluid is adequate except for the possible presence of enzymes. Both peritoneal fluid and transudates contain about 95% water. Traces of other constituents usually are expressed in milligrams per 100 cc. of fluid. The average cholesterol content of transudates is lower (40 mg. per 100 cc.) than that of peritoneal fluid (60 mg. per 100 cc.), but there is a wide range of variability. Both concentrations are much lower than that of cholesterol in plasma (195 to 230 mg. per 100 cc.). Peritoneal fluid shows lower average concentrations in total nitrogen, albumin, and creatinine than do transudates. The pH of the two types of fluid is practically the same (7.4), as are the average content of chlorides, nonprotein nitrogen, urea nitrogen, and uric acid. Further details are given in the Handbook of Toxicology (edited by W. S. Spector, National Research Council, Philadelphia, W. B. Saunders Company, 1956).

OSCILLOSCOPE RADIATIONS

To the Editor:—*A patient has chronic erythema and edema of his eyelids and across the bridge of his nose. The findings are those of a contact dermatitis. The history reveals the use of an oscilloscope screen (5BP1-zinc orthosilicate) for observing electrical wave forms. The patient has spent as long as five hours at a time working with this instrument at a distance of about 14 in., although he states he averages only about one hour a week. Could this be the cause of his trouble?*

Edwin R. Ruskin, M.D., New Rochelle, N. Y.

Answer.—Although this query is lacking in much needed information, such as the wearing of spectacles, it is possible to state that any oscilloscope operating in good condition provides less threat of injury than equal exposure to a television screen. While some ultraviolet rays are generated, these are completely absorbed by the covering glass of the oscilloscope. The x-ray radiation is trivial in amount and soft in quality. Even at high relative acceleration potential the prospect of injury is less than that from the television screen. In the United States there are hundreds of scientists who for years, day in and out, have observed the oscilloscope screen without any record of injury at any time. It is stated that the observation distance is only 14 in. This, if true, might be conducive to more eye strain than in the case of a greater observation distance. Even so, eye strain would not account for the reported damage to the nose. Therefore, the condition described can have no connection to the power entering the oscilloscope or to any emanation therefrom.

CHRONIC ATROPHIC POLYCHONDRITIS

To the Editor:—*Is there a disease which has as one of its principal characteristics softening of the cartilages in the trachea and bronchi? This question concerns a patient whose larger bronchi and trachea tend to collapse on forceful inspiration and who is troubled with atelectasis.*

M.D., Minnesota.

Answer.—A rare disease, chronic atrophic polychondritis, is characterized by inflammatory destruction, degeneration, and fibrous replacement of cartilage throughout the body. It is likely to be prominent in the ears and in the cartilaginous portion of the nose. Some or all of the joints may be involved, as well as the costal cartilages, the larynx, and the entire tracheobronchial tree. The condition is often preceded by or associated with iritis or iridocyclitis. No infecting organisms have been found. Some patients respond well to treatment with steroids. While such a condition might be confined to the trachea and the large bronchi, such a case has not been reported. The nature of this condition is unknown, but it has been suggested that it is a peculiar form of allergic reaction. Chronic pulmonary disease with atelectasis, infection, and respiratory insufficiency has been the cause of death in the fatal cases.

RADIO TRANSMISSION THROUGH FILLINGS

To the Editor:—*A 32-year-old woman who has many silver fillings in her teeth, who is otherwise physically in good health, and whose only diagnosable disease is a chronic anxiety state claims that for many years she has been able to hear radio programs even when the radio is not turned on. This occurs from time to time, and if she turns on the local station she finds that what she has been hearing in her ears is the same program that is currently playing. She lives with her husband on a farm, and there is no neighbor's radio nearby. It has been said that occasionally silver fillings can do this sort of thing. Is this legend or fact?* *M.D., Ohio.*

Answer.—When certain metals and their oxides are in a strong signal field of a radio transmitter, rectification may occur with the reception of the signal without the usual receiving equipment. This has occurred from radiators, faucets, and electric stove heating units but never from amalgam restorations or fillings. It is assumed that the farm on which the patient lives is not near a powerful radio transmitter. If so, a more intensive study of this unusual complaint should be made to determine whether other members of the household hear these radio programs. If the programs are heard only by the patient, the diagnosis and treatment are obvious. In view of the known anxiety state of the patient, the chief complaint should be evaluated more critically.

TREATMENT OF POISONOUS SNAKE BITES

To the Editor:—*The comments on treatment of poisonous snake bite, which appeared in the Questions and Answers section of* The Journal, *Jan. 3, 1959, pages 164-165, give the impression of being the latest information with which all are in agreement. This is not true, however, and the reader should realize that they represent Mrs. Buckley's personal feelings. It is unfor-*

tunate that this has resulted in the manufacturer's deleting reference to incision and suction in the circular accompanying their antivenin. Much work has been done regarding the effects of snake venom on animals. This has led to various conclusions, many of which do not apply to man. Due to the very nature of the problem, there are no well-controlled series evaluating the various therapies. There is little doubt, however, that the emphasis is shifting from incision, suction, and application of the tourniquet to more liberal use of antivenin, but this does not mean that the older techniques are without value if sensibly applied. The use of an arterial occlusive tourniquet is contraindicated, but the use of a tourniquet to block lymphatics is indicated. Much of the venom is transported via the superficial lymphatics, and the envenomation does not become systemic until these communicate with the deep lymphatics at the axilla, popliteal area, thigh, or groin. These superficial lymphatics can be blocked with a tourniquet loose enough to permit adequate arterial and venous circulation. Incising fang marks only compounds local damage from the venom, but incising the advancing edema front plus suction does remove a significant amount of venom. This was demonstrated by Jackson 30 years ago (South. M. J. 22:605, *1929). One must be careful in evaluating the results of therapy because of the many variables in a snake bite. Mrs. Buckley's suggested treatment would be adequate for most copperhead bites but would be inadequate for the bite of a large Florida or western diamondback rattlesnake. Many copperhead bites may need only antivenin, but a serious rattler bite will need incision, suction, tourniquet, adequate antivenin, and vigorous supportive measures, such as administration of blood, oxygen, and corticosteroids.*

John W. Schmaus, M.D.
University of Kansas Medical Center
Kansas City 3, Mo.

To the Editor:—*My letter in* The Journal *of Jan. 3, 1959, on the subject of snake envenomation, is not merely an expression of personl opinion but a compilation of medical opinion, published and in process of publication, on which the new, officially approved direction circular is based. Nowhere have I stated that "all are in agreement." The direction circular states, "Use of a tourniquet, incision and suction was for centuries the only method available for management of envenomation; such measures are still used by some physicians. However, others are coming to the opinion that surgical intervention should not be necessary if serotherapy is adequate." Much work has been done with the effects of snake venom in animals. Contrasting the results of Dudley Jackson, all Parrish's envenomated dogs, that were treated with incision and suction only, died. Although lymphatic spread of the venom received in the bite does take place, according to published reports, it is now believed that this is not the whole story. Parrish, whose work is summarized in the direction circular, stated that if any significant amount of venom is to be removed locally, early rather wide excision is required. Miller pointed out that this would be impossible on the foot, ankle, anterior surface of the leg, hands, and forearms. Parrish also emphasizes that "wide excision of any suitable body area would, of course, entail subsequent plastic surgery."*

The armed services were concerned with the question of the most satisfactory method for treatment of envenomation, because of snakebite accidents to military personnel. The studies of Leopold and co-workers and the observations of other authorities culminated in the request by the armed services for a new antivenin package from which the suction device is eliminated. This new package has been developed and has been officially standardized for military use.

The recommendations for dosage as given in the new direction circular reflect the experience of a number of clinicians practicing in snake-infested areas, as follows:

"INITIAL DOSE. It is essential to inject a large enough initial dose to overwhelm the poison. The smaller the body of the patient, the larger the initial dose required. Because children have less resistance and less body fluid with which to dilute the poison, they may require twice the dosage of serum that suffices for adults.

"Inject the contents of 1 to 5 vials of Antivenin or more, depending on the size of the snake, the lapse of time between the bite and specific treatment, and the size and condition of the patient (severity and rapidity of development of symptoms). For bites by large rattlesnakes and large specimens of other crotaline species, especially the tropical varieties, at least 5 vials of Antivenin or more may be required. Seven to 10 vials have been administered as the initial dose in many cases. For adult patients, as those weighing 100 to 150 pounds or more, 1 vial may be sufficient to neutralize the venom from the less virulent species, especially those of moderate size; e. g., copperheads or pygmy rattlers. For a bite by a similar specimen in a 20 to 40 pound patient, 3 to 5 vials may be required. Envenomation by a large cottonmouth moccasin may necessitate use of as large an initial dose as that for bites by rattlesnakes.

"ADMINISTRATION. If the bite was inflicted on an extremity, inject part of the initial dose intramuscularly (into muscle) or subcutaneously (under the skin) at various points around the limb, above the level of the swelling. Inject the rest of the initial dose into a large muscle higher on the bitten limb (the outer side of the thigh, the buttock or upper arm). Do not inject the serum into a finger or toe" (Shannon).

"If the bite was inflicted on the head or trunk, inject the initial dose subcutaneously or intramuscularly about the edges of the swelling surrounding the wound. Antivenin also may be injected subcutaneously in the loose tissue of the abdominal wall or between the shoulder blades. If a large amount of venom has been introduced directly into a superficial vein, as in a bite on the face, it may be desirable to inject Antivenin intramuscularly or intravenously within a few minutes. For late-treated patients exhibiting systemic symptoms, and especially in grave cases, associated with coma or paralysis, large doses should be administered intravenously."

The reported experience of Ruggiero showed that adequate antivenin treatment was effective in a severe case of Crotalus horridus (timber rattler) envenomation. Under local measures the patient's condition deteriorated rapidly, and he was moribund when antivenin was administered but recovered rapidly when mechanical measures were discontinued and adequate serotherapy was applied.

Supportive measures are described in the direction circular, in part, as follows: "The patient's blood should be typed as early as possible, since hemolysins present in the venom soon alter protein structure, thus preventing accurate cross-matching" (Shannon). "ACTH and cortisone may be used as a supplement to specific treatment, to control urticaria and similar delayed manifestations of allergy to horse serum, antibiotics and the venom itself. Such agents, however, do not of themselves influence the outcome of snake poisoning" (Wood, Hoback, Green; Schöttler). "Doses of 25 mg. cortisone have been administered by mouth, beginning with the first injection of serum, and continuing every six hours until all symptoms of envenomation were under control and no further doses of serum were required." According to one observer (Hoback) "such treatment has aided in reducing morbidity and has prevented evidences of serum sensitivity, even in known serum-sensitive patients. In severe cases cortisone may be administered intramuscularly or by vein if necessary."

Laboratory and clinical evidence has shown that the new, improved antivenin, released in March, 1954, does neutralize the proteolytic enzymes as well as the other toxic factors present in crotaline venoms. It is quite true that neutralization of the venom with antivenin is the only measure (officially) recommended. Infiltration of antivenin around the site of the bite is not advised in the newly revised direction circular.

According to properly constituted authority, cryotherapy is interdicted as a form of treatment. The new, approved direction circular states that this method, "first advocated for envenomation by Crum in 1906, has no therapeutic value" (Shannon, Parrish, Wood, and numerous others) "and is to be avoided as a form of treatment." "Combination of ligature and crymotherapy was tried and discarded (Allen) because such measures failed to save the lives of experimentally envenomated animals" (Allen). "Chilling, by chemical or other means, produces no alteration in the toxicity of the venom," (Shannon, Wood). "Prolonged exposure to cold is liable to increase the damage (Shannon). Since cold arrests conduction in the sensory nerves, however, ice water has been applied temporarily, by compress, in an effort to reduce the pain until serum could be administered. After injection of an adequate initial dose of Antivenin, application of cold is unwarranted and should be discontinued."

I shall be happy to send copies of the new direction circular on request.

BACTERIOPHAGE TREATMENT OF STAPHYLOCOCCIC INFECTIONS

To the Editor:—*In the Nov. 8, 1958, issue of* The Journal, *page 1423, is a question on bacteriophage treatment of localized or systemic staphylococcic infections. The answer states that "today there is no practical method of employing bacteriophage therapy in the treatment of staphylococcic infections." This statement requires additional elucidation. The therapy is little used and little understood, but it probably represents the approach of the future. In the Communicable Disease Section of the Los Angeles County General Hospital, cures of staphylococcic meningitis and overwhelming septicemia have been effected with freshly made preparations lysing the patients' organisms. The preparations were given intravenously in both cases as well as intrathecally in the case of meningitis.*

Albert G. Bower, M.D.

To the Editor:—*In the Question and Answer Section of* The Journal, *Nov. 8, 1958, page 1423, the consultant says that the great hope that bacteriophages would serve as effective thera-*

peutic agents against staphylococcic infections has never been realized. However, there is evidence that, when Staphylococcus bacteriophages prepared specifically for therapeutic purposes are used, they are of value. Practically all Staphylococcus bacteriophages have little, if any, effectiveness in vivo because they are inactivated rapidly in the presence of whole blood, serum, and pus. Such bacteriophages usually are prepared against a single strain or a pool of staphylococci in nutrient broth or peptone-free broth, and in these highly artificial conditions they do possess demonstrable and consistent lytic power. In my experience, however, such bacteriophages are useless as therapeutic agents.

Staphylococcus bacteriophages that act effectively in whole blood, serum, and pus can be prepared. For therapeutic purposes only those bacteriophages should be used that are virulent for the offending strain of Staphylococcus in the presence of the specific patient's whole blood, serum, or purulent exudate. It is also important that the bacteriophage to be used therapeutically can bring about lysis or convert the strain from smooth to rough at a temperature similar to that of the patient from whom the organism was isolated. Staphylococcus bacteriophages that have these attributes and are administered correctly can be useful in the treatment of local or systemic staphylococcic infections.

Morris L. Rakieten, M.D.

Islip, N. Y.

To the Editor:—*In* The Journal, *Nov. 8, 1958, page 1423, the reply about the presently accepted opinion of bacteriophage treatment of localized or systemic staphylococcic infections states that today there is no practical method of using bacteriophage therapy in such conditions. On April 1, 1958, the Lincoln Foundation, a nonprofit medical research organization with laboratories in Swarthmore, Pa., was granted U. S. Government License 299 for Bacterial Antigen–Staphylococcus Phage Lysates (Staphage Lysates-T. M.). New biological products today must pass rigid criteria and strict evaluations with evidence of the need and merits and safety before such license is issued. Administered by nasal aerosol, orally, and topically, Staphage Lysates provide a practical method of controlling staphylococcic infections which concentrates on an immunological and lytic approach to this increasingly serious problem. This super-vaccine with highly polyvalent phage activity enhances the natural, active defensive mechanisms of the host by lysing pathogenic staphylococci in their main habitat, the anterior nares. Staphage Lysates selectively kill Staphylococcus pyogenes var. aureus yet spare the useful saprophytes of the intestinal flora, so essential in the bacterial synthesis of vitamins. The lysates contain bacterial polysaccharides which have been shown to be a potent agent for stimulation of higher levels of serum properdin, providing a nonspecific immunity against invasion by all bacteria and viruses. Many of the older articles on bacteriophagy stressed the value of specific staphylococcic phages in the treatment of staphylococcic infections (Crutchfield and Stout,* Arch. Dermat. & Syph. *22:1010, 1930).*

I have contacted most of the competent authorities in the investigative field dealing with antibiotics. Laboratory studies with clinical evaluations are being conducted on many fronts, the results of which will be published soon. The emergence of resistant strains of Staph. pyogenes var. aureus shows that the probable answer to this perplexing problem may not lie in the development of more new antibiotics, or combinations of them, but in the host, his environment, and his protective mechanisms. Being a nonprofit group, the trustees of the Lincoln Foundation have not applied for a patent on their product, but they do wish to disseminate the more recent knowledge of staphylococcic phages gained in the past 12 years of intensive work with Staphage Lysates. We have profited immensely from the background of mistakes and truths obtained during the 1920's and 1930's when bacteriophage was in its heyday. These facts warrant a critical reappraisal of staphylococcic bacteriophagology in the fight to overcome the serologic supremacy of the pathogenic micrococci, especially since resistance to phagic lysis has not been observed and the "hot" epidemic, hospital strains of Staph. pyogenes var. aureus—phage pattern 80/81—are readily lysed by Staphage Lysates.

MUSCLE CRAMPS

To the Editor:—*In* The Journal, *Dec. 20, 1958, page 2206, a question was asked relative to the treatment of muscle cramps. Years ago, a patient began having cramps in the legs at night and a colleague suggested the use of quinine sulfate, which he had given for years, with success. Since then, from personal experience and in patients, regardless of any rationale, it has worked, which seems to be sufficient justification for its use. One 0.3-Gm. capsule has usually been sufficient to ward off the attacks for weeks and often months. Failure has been extremely rare.*

ORAL CHOLANGIOGRAPHY

A METHOD OF VISUALIZING THE "NONVISUALIZED" GALLBLADDER

J. Russell Twiss, M.D.
and
Lee Gillette, M.D., New York

Forty-six patients were selected for further study after routine cholecystography had failed to give satisfactory visualization of the gallbladder or bile ducts. When oral cholangiography was carried out in this group, there was visualization of the gallbladder or of the common bile duct with stones in 23 patients, visualization of the gallbladder without stones in 12, and no visualization in 11. Of these 11, 8 were operated on and were found to have obstructed cystic ducts. Three of these had acute cholecystitis, with gangrene in one. Nine patients were spared an operation when oral cholangiography demonstrated normal function and absence of stones in the gallbladder. Resort to oral cholangiography is therefore to be recommended when routine cholecystography fails to give decisive results, for it gives 65% additional visualization as compared to only 5 to 10% additional visualization with the double dose method.

THE PURPOSE of this investigation was to compare the results of oral cholangiography with those of intravenous cholangiography in revealing actual pathological conditions when routine oral cholecystography gave no visualization of the gallbladder, bile ducts, or stones. We herewith report the results obtained with our own technique of oral cholangiography. The procedure used is a modification of one previously described.[1] Forty-six patients are included in this report. Routine cholecystography had failed, in all cases, in visualization of the gallbladder. However, oral cholangiography did reveal shadows of the gallbladder, with or without stones, in 33 patients (65%).

Routine cholecystography results in nonvisualization of the gallbladder and bile ducts in about 10% of tests made. Routine repetition of the cholecystography, with a double dose of dye, gives additional information in only a small proportion of cases. In absence of jaundice or evidence of impaired liver function, nonvisualization of the gallbladder is presumptive evidence of pathological changes, usually with cystic duct obstruction. However, it

---

Presented, in part, as an exhibit before the World Congress of Gastroenterology, Washington, D. C., May 25-30, 1958.

has long been known that these findings may not be evident at operation. Under these circumstances, cholecystectomy either fails to relieve the preoperative symptons or aggravates them in about half the cases.

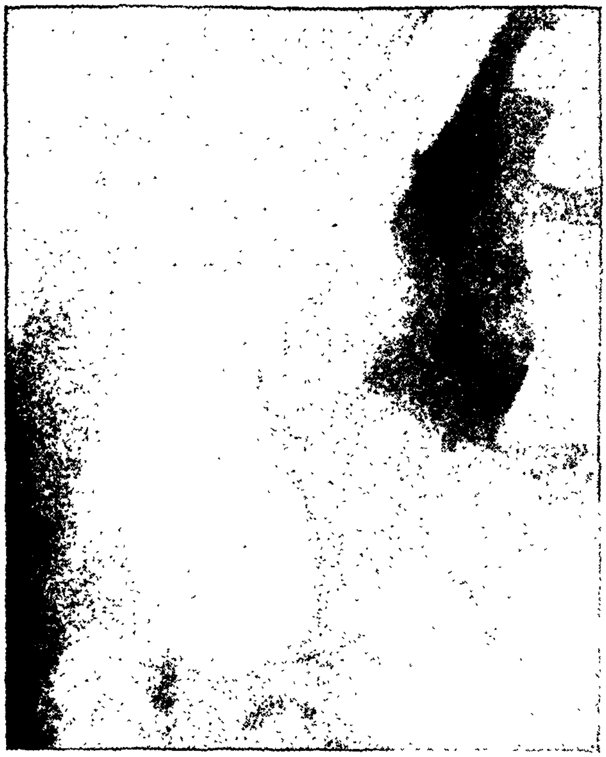

Fig. 1.—*Oral cholangiogram, showing normal visualization of the gallbladder without evidence of stones.*

Further information concerning the nonvisualized gallbladder may be obtained by intravenous or oral cholangiography. In the case of complete cystic duct obstruction ("physiological cholecystectomy"), both methods will fail to reveal a gallbladder shadow. As for partial obstruction of the cystic duct, most investigators have reported that iopanoic acid (Telepaque) is a more accurate indicator of disease because the intensity of the gallbladder shadow is dependent on its concentrating ability.[2] The triple dose of dye is used when a period of time has elapsed after the routine cholecystogram has been taken.

Instructions for patients with a previously nonvisualized gallbladder were as follows: On the evening before the roentgenograms were to be taken, the patient was given, at 7 p. m. (after 6 p. m. supper), 6 tablets of iopanoic acid with a glass of water. This was repeated a half hour later. At 9 p. m., 1 teaspoonful of paregoric in a glass of water was given. No fluids were to be taken during the night (other than specified). On the day the roentgenograms were to be taken, no breakfast wa allowed; at 7 a. m. the patient was given 6 tablet of iopanoic acid with a glass of water, and at 9 a. m the patient was given paregoric, 2 teaspoonfuls i one-fourth glass of water. The roentgenogram were taken at 10 a. m. and repeated at 11 a. m. an at noon. If no visualization of the *bile ducts* wa obtained, the films were repeated 24 hours later.

Results of Present Investigation

Forty-six patients are included in the report he presented. The patients were selected for study b the technique described because routine or cholecystography and, in some cases, intraveno cholangiography had shown inadequate or n visualization of the gallbladder or bile ducts. In n case was any specific diagnosis possible by previo roentgenographic tests.

For purposes of discussion, the patients a grouped on the basis of the results obtained wi oral cholangiography: (1) visualization of the ga bladder or of the common bile duct with ston 23 patients, (2) visualization of the gallbladd without stones, 12, and (3) no visualization of t gallbladder, 11 (in 6 of these the common duct w seen).

Stones were visualized in 23 patients in wh either gallbladder or common duct was seen. In t 18 patients of this group who were operated o roentgenographic findings were confirmed in cases. In 3 of the 18, there was visualization of t cystic duct up to the point of calculous ampul occlusion.

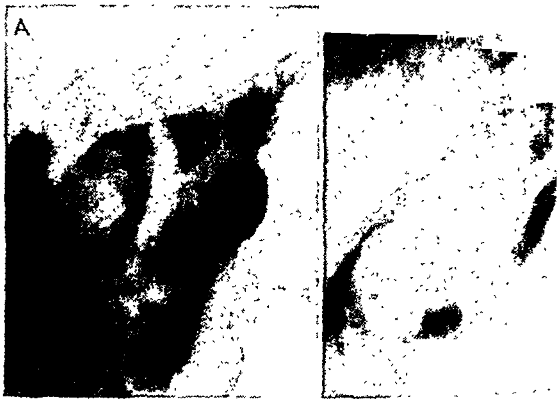

Fig. 2.—*Oral cholangiograms, showing, A, only comm duct and, B, common duct and cystic duct, with calcul ampullar obstruction.*

In the 12 patients with no stones and visuali tion of the gallbladder but not the common duct were operated on. Of these three, two had steno of the common duct sphincter without stones a one had acute cholecystitis. This patient had no stones in the gallbladder and one stone in the common duct. Thus, operation revealed common duct obstruction in each of the patients having no visualization of the common duct.

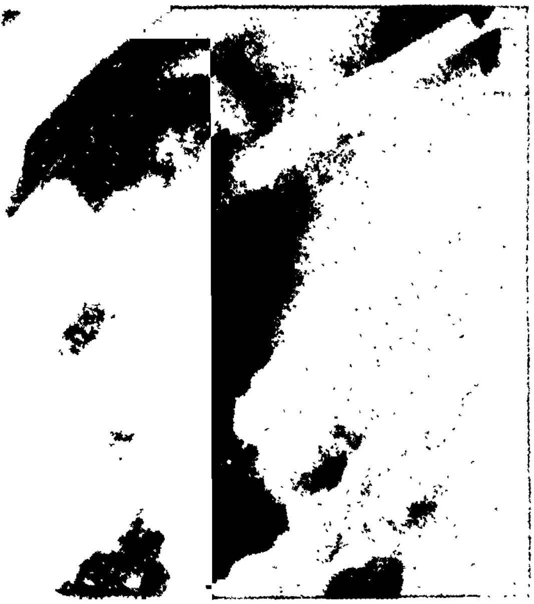

Fig. 3.—Oral cholangiogram, showing common duct and good visualization of gallbladder which contains multiple stones.

Of the 11 patients without visualization of the gallbladder, 8 were operated on. All had cystic duct obstruction. In six cases, the diagnosis was cholecystitis with cholelithiasis. In three of these, the condition was acute. Of these three patients, two had stones and one had gangrene of the gallbladder without stones.

Of these 11 patients, 6 had visualization of the common duct but not the gallbladder. Findings in the common duct were as follows: In three, the oral cholangiograms showed the common duct to be normal. In two of these three patients operated on for chronic cholecystitis with cholelithiasis, the common duct findings were confirmed. In the three patients in whom the oral cholangiograms showed dilated common ducts, the findings were confirmed at operation. In two of these patients the diagnosis of stones in the common duct, seen on the films, was confirmed at operation. In the third patient two small stones, found in the common duct at operation, were not seen in the films.

In summary, 33 patients had visualization of the gallbladder; an additional 6 had visualization of only the common duct. Twenty-seven patients were operated on. In 25 cases the diagnosis made by oral cholangiogram was confirmed at operation.

Diagnostic Use

Following is a discussion of findings in various conditions, including liver disease, catarrhal cholecystitis, pathological cystic ducts, chronic cholecystitis, and chronic cholecystitis with choledocholithiasis.

Disorders of the Liver.—As was previously noted, jaundice or impaired liver function will usually prevent visualization of the gallbladder by either the intravenous or the oral method. However, in certain patients without jaundice, oral cholangiography may clarify an otherwise obscure diagnosis.

Catarrhal Cholecystitis.—The group with catarrhal cholecystitis includes patients having relatively mild symptoms of gallbladder disease. In 25% of the patients of this series, oral cholangiography showed normal visualization and emptying of the gallbladder, without evidence of stones. This is illustrated in figure 1, an oral cholangiogram of a patient in whom, previously, a routine cholecystogram with a double dose of contrast medium had given no visualization. The patient was spared an operation.

Pathological Cystic Ducts.—Complete cystic duct obstruction will prevent visualization of the gallbladder by any method of cholangiography. However, oral cholangiography may reveal, under these circumstances, a common duct or, at times, visualization of the cystic duct up to the point of calculous obstruction (fig. 2). Patients of this series, with these cholangiographic findings, at operation showed hydrops of the gallbladder and acute or chronic cholecystitis, usually with cholelithiasis.

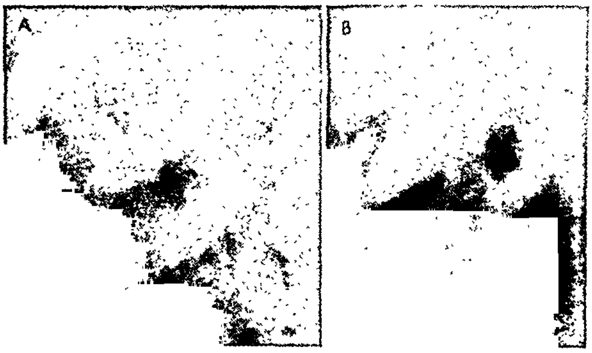

Fig. 4.—*A*, intravenous cholangiogram, showing only common bile duct (routine cholecystogram had twice shown no visualization). *B*, oral cholangiogram in same patient, showing common duct and faint visualization of gallbladder containing multiple negative shadows (operative findings included chronic cholecystitis with multiple stones and common duct normal, containing no stones).

Chronic Cholecystitis.—The greatest field of usefulness of oral cholangiography lies in furnishing definite diagnostic information in those patients with diseased gallbladder and partial cystic duct obstruction (fig. 3). Even in those patients in whom intravenous cholangiography has not given visualization of the gallbladder, oral cholangiography may be successful (fig. 4).

Chronic Cholecystitis with Choledocholithiasis.—Patients with diseased gallbladder and common duct stones may have visualization of neither the gallbladder nor the common duct, even with intravenous cholangiography. Due apparently to the longer period of dye excretion and concentration, oral cholangiography may reveal definite information under these conditions (fig. 5).

Combined Oral and Intravenous Cholangiography

In certain cases, where the use of oral cholangiography by the multiple dose technique results in no visualization or an unsatisfactory visualization, the addition of intravenously given iodipamide (Cholografin) may clarify the diagnosis. The injection may follow the third hourly oral cholangiogram or, preferably, be given after a period of 24 hours. After the dye is given intravenously, films are taken at 20-minute intervals for one hour or for two hours if the gallbladder is present. Figure 6 shows the results of such a procedure in a patient in whom the routine oral cholecystogram had shown no visualization.

Summary

A series of 46 patients, who on routine cholecystography had no visualization of the gallbladder or bile ducts, was studied with use of oral cholangiography. By this method, visualization of the gallbladder was obtained in 33 (65%). In 23 patients, oral cholangiography revealed stones not seen by means of oral cholecystography. Eighteen of these patients were operated on, and the diagnosis was confirmed in 17.

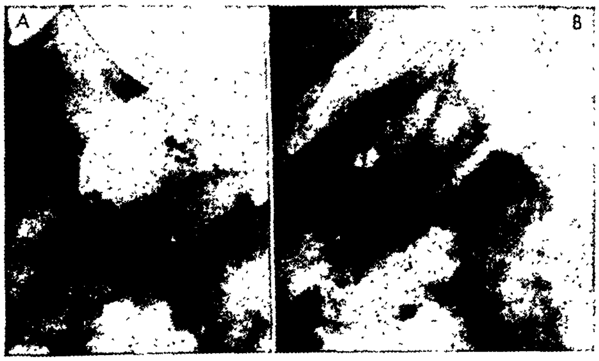

Fig. 5.—Oral cholangiograms, showing, *A*, gallbladder and dilated common duct, both with multiple stones and, *B*, faint visualization of gallbladder (*arrow*) and good visualization of common duct with choledocholithiasis (findings were confirmed at operation).

In 9 patients, oral cholangiography revealed normal gallbladder function and absence of stones. These patients were spared an unnecessary operation. These facts indicate that the gallbladder not visualized by routine cholecystography should be reexamined by oral cholangiography.

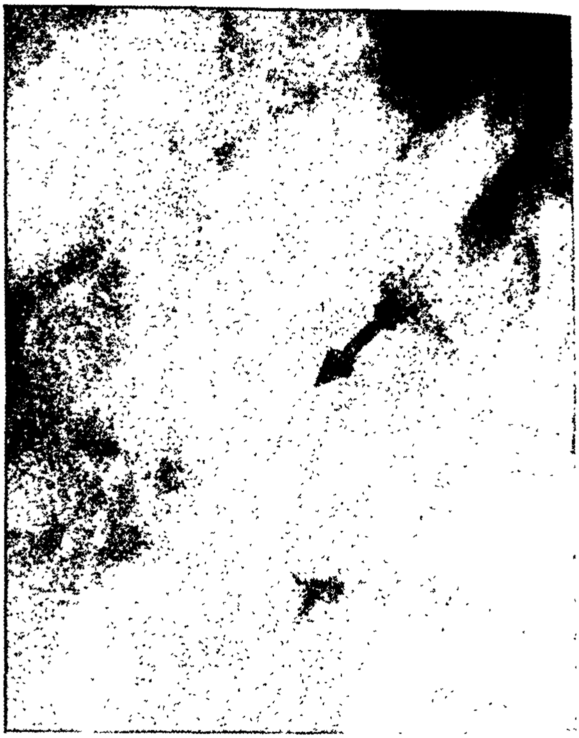

Fig. 6.—Combined oral and intravenous cholangiogram showing widely dilated common duct and gallbladder containing multiple stones. Oral cholangiogram had shown good visualization of the gallbladder and faint visualization of dilated common duct (*findings were confirmed at operation*).

SIMPLIFIED SCREENING TEST FOR CYSTIC FIBROSIS OF THE PANCREAS

Edwin M. Knights Jr., M.D., James S. Brush, Ph.D.
and
John Schroeder, Flint, Mich.

A test paper has been devised for use in quick examination of large numbers of people to detect increased concentrations of chloride in the sweat. The paper is impregnated with silver chromate, which is red. Upon contact with a solution of sodium chloride the red color is replaced by the white color of silver chloride. The paper was found easy to prepare, store, and apply, and after use it could be kept with the records of the case. Used in 91 healthy subjects and 9 patients known to have cystic fibrosis of the pancreas, it gave 3+ reactions with all the latter group. False-positive results were obtained in some children with fever or under emotional stress. Relatively strong (2+) reactions were obtained in some parents of children with cystic fibrosis, which is known to be inheritable.

Measurement of the chloride excreted by sweat glands in the hand has become a well-established diagnostic screening procedure for cystic fibrosis of the pancreas. It owes its inception to an astute clinical observation by Kessler and Andersen[1] during the New York City heat wave in August, 1948, that seven of the children hospitalized with heat prostration had cystic fibrosis of the pancreas. Elevated sweat chloride concentration in children, accompanied by relevant clinical data, is now usually considered strongly suggestive of cystic fibrosis and an indication for further diagnostic studies.

A simplification of the sweat test was reported by Shwachman and Gahm[2] in 1956. This method uses silver chromate in an agar base to assess the amount of chloride in hand sweat. As there is evaporation of water from the hand, the results are not a true indication of chloride concentration in hand sweat, but the test can be used for relative comparison between normal and diseased persons. This test has proved to be a most valuable screening procedure but it has some inherent disadvantages: The agar plates are bulky and must be refrigerated during storage; children tend to dig their fingers into the agar during testing; and the method provides no permanent record of the reaction.

A modification of this method was reported by Webb and Geiger[3] in 1957. The authors used a piece of filter paper on which a drop of 2% silver nitrate solution had been placed. The paper was grasped between thumb and forefinger by the test subject, and 10% potassium chromate solution was dropped on the filter paper. Increased sweat chloride levels were indicated by a light thumbprint on a dark background.

Simplified Test

These testing procedures have been further modified, and, we believe, simplified, by the impregnation of filter paper with silver chromate. In our tests we used no. 1 Whatman filter paper, 11 cm. in diameter. This diameter provides a complete hand print for most children.

The filter paper was dipped into 0.2 *N* silver nitrate solution, removed, blotted gently, and allowed to dry completely. The dried filter paper was then immersed in 0.2 *N* potassium chromate solution. It must enter this solution vertically so that both sides are exposed equally. Papers were then washed with distilled water to remove excess potassium chromate and immediately withdrawn and blotted. Prepared papers may be stored moist in an airtight container (we used plastic Petri dishes), or they may be dried and remoistened with water when ready for use. Papers must be kept in the dark; we have kept them for several months without any significant deterioration.

Testing Procedure and Results.—Fingerprints were made from the unwashed hands of test subjects and repeated at intervals up to 20 minutes after washing. For proper evaluation it was found necessary to wash the hands of the subjects; the best readings were made after a waiting period of 15 minutes. During this period it is desirable to protect the hand from contact with other parts of the body. For this purpose we used a fenestrated plastic football with an enlarged opening at one end. The child's hand was placed inside and the football secured in place by a gauze bandage.

Test papers must be moist when used. If stored dry, they should be remoistened with distilled water or tap water low in chloride content just prior to testing. They should be blotted gently before use, as prints are more distinct if the paper is not excessively wet. In testing, the patient's

---

A and *B*, hand prints from children with cystic fibrosis of the pancreas, both graded 3+. *C*, test on normal child.

hand is pressed (with moderate pressure), pal down, onto the filter paper and held there f three or four seconds. In our experience it was n necessary to control precisely the length of tim that the hand is in contact with the filter pape as the available chloride is precipitated ve rapidly.

A result can be read immediately by compari the print to that of a normal control or to phot graphs of various prints. If the normal control pri is made at the time of the testing it must be membered that no relatives of patients should used as normal controls because of the heredita nature of the disease. Results are graded 1+, 2 and 3+ as suggested by Shwachman and Gahm False-positive results may occur in tests on febr children and those under considerable emotio stress.

Testing of 91 normal children and adults a 9 persons with known cases of cystic fibrosis vealed results similar to those obtained by t agar plate method (see figure). Reactions in p tients with cystic fibrosis all fall in the gro arbitrarily classified as 3+. All of these patie gave relatively heavier prints with the volar s faces of the proximal and middle phalanges the full hand print was taken, relatively hea ridges in the print of the palm were also observe Indistinctness of the print due to heavy blotchi was also characteristic of certain of the tested p tients with cystic fibrosis. Relatively strong (2+) actions have been encountered in some parents patients with known cases of cystic fibrosis. Af testing, the silver chromate-coated papers w dried at room temperature in a dark location. Th remained stable and provided a lasting record the reaction.

Summary

The impregnation of filter paper with sil chromate provides an improved method of scre ing children for cystic fibrosis of the pancreas. is similar to the agar plate test now widely us but has the added advantages of being less pensive to prepare and much easier to store, a it provides a lasting record of the reaction.

This study was aided by a grant from the Ames Comp Inc., Elkhart, Ind.

RELATION OF FIBROSIS OF THE PANCREAS TO FATTY LIVER AND/OR CIRRHOSIS

AN ANALYSIS OF ONE THOUSAND CONSECUTIVE AUTOPSIES

Edward E. Woldman, M.D., David Fishman, M.D.
and
Abraham J. Segal, M.D., Cleveland

For the past 35 years, the association of pancreatic disease and fatty infiltration of the liver with subsequent fibrosis has been observed frequently. Allan and associates[1] have shown that depancreatized dogs developed marked fatty infiltration of the liver even while they were maintained on therapy with an adequate amount of insulin. Montgomery and associates[2] were able to produce fatty changes in the liver of dogs after ligation of the pancreatic ducts.

It has been demonstrated by Dragstedt and associates[3] that feeding these animals raw pancreas prevented the development of fatty livers. Hershey and Soskin[4] have shown that the oral administration of lecithin has the same effect, and Best and Huntsman[5] have proved that choline, a derivative of lecithin, is also effective in preventing the development of fatty livers in experimental animals.

Later studies revealed that fatty livers were due to a deficiency of choline and other lipotropic substances resulting from the incomplete digestion and absorption of dietary protein in the absence of proteolytic enzymes of the external secretions of the pancreas.[6]

This experimental work on animals stimulated the interest in the development of fatty livers and cirrhosis in patients with diffuse pancreatic disease. Case reports began appearing in the literature dealing with fatty livers in patients with pancreatic disease. These included 2 cases of pancreatic lithiasis and atrophy reported by Snell and Comfort,[7] 2 of pancreatic fibrosis and atrophy by Cole and Howe,[8] and 10 of carcinoma of the pancreas involving the ducts and producing obstruction with secondary atrophy by Schnedorf and Orr.[9] All these cases were associated with fatty liver.

In the more recent reports, there were larger groups of patients with diffuse pancreatic disease with associated fatty livers. Edmondson and coworkers[10] found fatty liver in 17 (65%) of 26 patients with pancreatic lithiasis and chronic pancreatitis. Sanes and co-workers[11] found fatty changes and/or cirrhosis in all seven cases of pancreatic lithiasis. These studies were made on data from postmortem examinations.

The possibility that fibrosis of the pancreas might be related in some way to disease of the liver was explored in a study of material from 1,000 consecutive autopsies. Among these, 778 were free from disease of the liver; in the remaining 222 there was either fatty infiltration or cirrhosis or both. Fibrosis of the pancreas was present in 234 cases and absent in 766. There were 156 cases in which fibrosis of the pancreas was present together with involvement of the liver. This indicates a high degree of association between the two conditions.

There seems to be sufficient evidence both experimentally and in postmortem material to indicate that disturbances in pancreatic function may lead to fatty changes in the liver with subsequent fibrosis. In the early stages, the liver is fatty and the fatty change is important in the development of the later diffuse fibrosis. The next is the fibrofatty stage, and the advanced stage is the fibrotic stage. The present study is a report on 234 cases of pancreatic fibrosis and its relation to fatty liver and/or cirrhosis.

Material and Method

Our material was drawn from 1,000 consecutive autopsies at St. Luke's Hospital, Cleveland. The microscopic sections of the pancreas and liver were carefully reviewed by one of us (A. J. S.), and only those showing fibrosis of the pancreas were chosen for study. We did not include any case of acute pancreatitis, as we know that it takes several weeks or months of pancreatic insufficiency to produce a fatty liver. Fibrosis of the pancreas leading to pancreatic insufficiency is the end-result of severe or repeated damage to this gland. This condition is usually diagnosed at surgery or at postmortem examination and rarely diagnosed clinically.

We grouped the cases of fibrosis of the pancreas into three groups, those with fatty liver, those with fatty liver and cirrhosis, and those with cirrhosis. The first group was graded as mild, moderate, or severe, according to the degree of fatty change in

---

From the divisions of medicine (gastroenterology) and pathology, Saint Luke's Hospital.

the liver, and the second and third groups were graded as mild, moderate, or severe according to the degree of fibrosis.

Results

Fibrosis of the pancreas was observed in 234 (23.4%) of the 1,000 consecutive autopsies examined in our series. It occurred most frenquently during the fifth and sixth decades of life and was uncommon in the first two decades of life. The sex distribution was 131 males and 103 females (table 1). Of these 234 cases of pancreatic fibrosis, only 31 (13%) were with diabetes mellitus.

TABLE 1.—*Age and Sex Distribution of 234 Patients with Pancreatic Fibrosis*

Age Group, Yr.	Male, No.	Female, No.	Total
20-29	1	2	3
30-39	8	5	13
40-49	11	12	23
50-59	39	25	64
60-69	41	38	79
70-79	21	15	36
80+	10	6	16
Total	131	103	234

Fibrosis of the pancreas occurs in two major groups of patients, those with biliary tract disease and those who are chronic alcoholics. Among the 234 patients in our series there were 87 (37%) with associated disease of the biliary tract, such as cholelithiasis or cholecystitis. We were unable to obtain the exact data on the incidence of alcoholism in our series of fibrosis of the pancreas, as most of the cases were diagnosed during postmortem examination. Although a history of alcoholism was present in many cases, the data were insufficient for statistical purposes.

Of the 234 patients with fibrosis of the pancreas in our series, 156 (66.6%) showed either fatty liver alone or fatty liver and/or cirrhosis. There were 117 showing fatty liver alone, 32 showing fatty liver and cirrhosis, and 7 showing cirrhosis alone, or a total of 156 patients showing liver involvement (table 2). Among the entire group of 1,000 consecutive autopsies, there were 150 with fatty liver and 72 with fatty liver and/or cirrhosis, or a total of 222 patients with liver involvement. Of this total, 156 (70.3%) also showed pancreatic fibrosis.

Comment

A great deal of emphasis has been placed on the nutritional factors in the etiology of fatty liver and/or cirrhosis. The best evidence that nutritional factors are involved in the pathogenesis of fatty liver and cirrhosis comes from a consideration of kwashiorkor, which commonly occurs in tropical areas.[12] The diets of populations of the areas in which this syndrome occurs are low in protein, especially that of animal origin. In patients with kwashiorkor, in addition to changes in the liver, there have also been pathological findings of atrophy of enzyme-secreting cells of the pancreas, which may represent the primary lesion of kwashiorkor and may be responsible for the changes in the liver. We do not know the precise cause of the atrophy of these cells in the pancreas.

The association of alcoholism with fatty liver and cirrhosis was observed for many years and is now generally accepted. It has been observed by Patek and Post[13] that the conditions of patients with liver cirrhosis and a history of alcoholism improved when they received an adequate diet without cutting down on alcohol intake. The concept of cirrhosis in the alcoholic has been reoriented toward the nutritional aspects. There is no doubt that chronic alcoholics reduce their food intake to undernutritional levels. However, evidence of cirrhosis of the liver may occur in alcoholics who appear well nourished or, in fact, obese and may not be apparent in undernourished alcoholics.

Higginson and co-workers,[14] from their studies with such underprivileged Africans as the Bantu, doubt whether nutritional factors alone can be held responsible for the frequency of liver disease. Undernourished people in prison camps during World War II rarely showed evidence of liver involvement. A human diet deficient in lipotropic factors is hard to imagine and must be rare. Pancreatic insufficiency must be an important factor in causing a deficiency in lipotropic substances with the development of fatty liver and/or cirrhosis.

In most cases of alcoholism, as in kwashiorkor, pancreatic disease plays an important role in the development of fatty liver and cirrhosis. There is a rather high incidence of alcoholism in most reported series of acute and chronic pancreatitis.[15] Edmondson and co-workers[10] reported that 58.8% of their group of patients had a history of alcoholism, and Comfort has reported an incidence of 68%. There are other factors besides alcoholism which may be responsible for pancreatic disease, such as biliary tract disease. However, Owens and Howard[16] reported that 32 patients, who were diagnosed at Grady Memorial Hospital as having pancreatic calcification, were all chronic alcoholics.

TABLE 2.—*Incidence of Fatty Liver and/or Cirrhosis in 234 Cases of Fibrosis of the Pancreas*

	Mild, No.	Moderate, No.	Severe, No.	Total
Fatty liver	46	61	10	117
Fatty liver and cirrhosis	5	14	13	32
Cirrhosis	0	2	5	7
Total				156(66.6%)

Every patient was studied for evidence of gallstones by cholecystography, laparotomy, or autopsy and none were found.

McGowan and co-workers [17] have shown that hydrochloric acid and alcohol, when passing into the duodenum (after oral ingestion of alcohol), causes a spasm of the sphincter of Oddi. After large quantities of alcohol are taken orally, edema of the duodenal mucosa and papilla of Vater may also occur. This edema had been noticed in alcoholics at autopsy. From the results of experimental studies of Dreiling and co-workers [15] and from the investigative work of others, we can say that the role of alcohol in the production of pancreatitis is neither by the direct stimulatory effect on the pancreas nor through toxic action. Rather, it is suggested that the oral intake of alcohol causes the pancreas to secrete a large volume of pancreatic juice against an obstruction to the flow of secretion (spasm or edema). Rupture of the finer radicles of the pancreatic tree may result from the sudden increase in the intraductal pressure. Chronic pancreatitis is the end-result of many such episodes. Dreiling and associates [15] also found that when alcohol was administered intravenously in man to a point of intoxication it did not have any effect on the pancreas.

Clark [18] reported 44 cases of pancreatitis occurring in patients with acute and chronic alcoholism from autopsies at Bellevue Hospital, New York. In 24 the liver was large and fatty, and in 17 cirrhosis was present.

Pancreatic fibrosis results in pancreatic insufficiency due to the atrophy of the enzyme-secreting cells. The absence of the proteolytic enzymes of the external secretions of the pancreas causes incomplete digestion of dietary protein resulting in a deficiency of choline and other lipotropic substances. A deficiency of choline results in a deficiency of phospholipid synthesis and a failure of fat transport or oxidation, and, as a consequence, fat accumulates in the liver, leading to fatty liver with subsequent cirrhosis.

The so-called alcoholic cirrhosis or nutritional cirrhosis is not the result of a deficiency in dietary protein, as is frequently found in chronic alcoholics, but is, rather, the result of pancreatic insufficiency (due to disease of the pancreas) plus a low intake of dietary protein.

Summary

There is a definite relationship between fibrosis of the pancreas with pancreatic insufficiency and the development of fatty liver and/or cirrhosis. Reports in the literature have emphasized the fact that chronic alcoholism plays an important role in the etiology of fibrosis of the pancreas. The so-called alcoholic cirrhosis or nutritional cirrhosis is not the result of a deficiency in the dietary protein but is, rather, the result of pancreatic insufficiency plus a low intake of dietary protein.

BACTEREMIA DURING PARTURITION

PREVENTION OF SUBACUTE BACTERIAL ENDOCARDITIS

Capt. Paul D. Redleaf
and
Lieut. Col. Edward J. Fadell, (M.C.), U. S. Army

Blood samples for bacteriological study were obtained from 101 obstetrical patients immediately after delivery of the placenta, and again on the morning of the first postpartum day, in order to observe the frequency of bacteremia during labor. Four of the samples at the end of labor yielded bacterial growth, one organism being a coagulase-positive staphylococcus. Eleven of the samples obtained next day yielded growth, one organism being an alpha-hemolytic streptococcus. Thus, only two potentially pathogenic organisms were found, but the hazard of bacteremia in connection with labor was seen to be real. Patients believed to be susceptible to recurrent subacute bacterial endocarditis appear to need the same protection during parturition as is needed by similar patients during dental extractions, tonsillectomies, and urologic procedures. Prophylaxis with antibiotics is therefore justified in such cases.

Recognition of the transient bacteremia which frequently follows various operative procedures has resulted in successful prophylaxis against subacute bacterial endocarditis. The use of antibiotics in conjunction with dental extractions, tonsillectomies, and urologic procedures in patients with valvular or congenital heart disease is supported by careful bacteriological studies. Despite the occasional occurrence of subacute bacterial endocarditis after parturition, the hazard of bacteremia during normal labor has received no adequate documentation, to our knowledge. As a result, although most authorities endorse the prophylactic use of antibiotics in patients susceptible to bacterial endocarditis,[1] others omit this recommendation.[2] Therefore, it seemed appropriate to determine the incidence of bacteremia in normal labor and to review the pertinent clinical experience.

Materials and Methods

Specimens of blood were obtained in 101 consecutive patients immediately after delivery of the placenta, omitting only those patients with a history of recent antibiotic therapy for obstetric or medical reasons. Follow-up cultures were obtained in each case on the morning of the first postpartum day. The antecubital veins were used for withdrawal of blood after preparation with iodine and alcohol. Five cubic centimeters of blood was placed in Bacto-tryptose broth and 3 cc. was placed in thioglycollate broth. The cultures were examined for growth at the end of approximately one week. At the end of two weeks, in all instances, smears were made and transfers to blood agar plates were done. Incubation was aerobic and anaerobic, and the plates were kept for 48 hours before being discarded as negative.

Bacto-mannitol salt agar was utilized as a selective medium for the isolation of pathogenic staphylococci. The coagulase test was done on colonies having yellow zones. The ability to grow in a 6.5% sodium chloride solution was used to differentiate enterococci.

Results

Of the 202 samples taken from 101 patients, growth was obtained in 15, 4 in samples at the end of labor and 11 from blood obtained on the first postpartum day. In no patient did both samples on consecutive days reveal growth. Fourteen cultures yielded Staphylococcus (Micrococcus) species, most of these only in the thioglycollate broth. Only one was coagulase positive. A single alpha-hemolytic streptococcus was isolated in a postpartum specimen. This failed to grow in 6.5% sodium chloride solution and thus was not an enterococcus.

The patient with alpha-hemolytic streptococcus bacteremia proved to have been included in our study inadvertently. She had inactive rheumatic heart disease and had taken a sulfonamide daily prior to labor. Through oversight, she was given no antibiotic coverage during parturition. Six subsequent blood cultures were negative, however, and no clinical evidence of bacterial endocarditis appeared during the next two months.

The charts of the remaining 14 patients with positive cultures were reviewed. Only three had transient fever in the postpartum period. One had endometritis caused by a beta-hemolytic streptococcus, another had Escherichia coli pyelonephritis, and in the third the temperature elevation for one day was unexplained.

The percentage of staphylococcus isolations was no greater than that encountered in our laboratory

---

From the medical and laboratory services, Ireland Army Hospital, Fort Knox, Ky.

as contaminants in routine blood cultures. This interpretation is supported by the fact that all but one were coagulase negative. The single alpha-hemolytic streptococcus and the coagulase-positive staphylococcus were the only organisms which may be considered potentially pathogenic, especially the former because of its frequent isolation in instances of subacute bacterial endocarditis.

Comment

The rarity of bacteremia after parturition in this study does not invalidate the recommendation that prophylaxis against bacterial endocarditis be used in susceptible patients. Our data indicate the minimum rather than the maximum possible incidence of postpartum bacteremia. An important bacteremia may be extremely transient, as was demonstrated in studies after dental extraction by Okell and Elliott.[3] We deliberately obtained initial cultures at a time when placental sinusoids are maximally dilated; nevertheless, more frequent cultures might have yielded a larger number of positive results. However, in an unpublished study by Ramsey and Swartwout,[4] 74 blood cultures obtained in 17 patients during and at various intervals after labor were uniformly negative.

Despite its low incidence, the seriousness of bacterial endocarditis warrants the use of prophylactic therapy in patients with predisposing heart disease. Of Wheeler's 200 cases of subacute bacterial endocarditis, 9 were precipitated by abortion or delivery.[5] In the extensive British experience reported by Cates and Christie,[6] the three postpartum cases of endocarditis were each caused by alpha-hemolytic streptococci. One case followed abortion; in this an enterococcus was isolated. In Geraci and Martin's study[7] of 33 cases of enterococcic endocarditis, one resulted from normal delivery, another followed dilation and curettage, and three more followed abortion. A questionnaire survey and review of the literature by Pedowitz and Hellman[1d] revealed 120 cases of bacterial endocarditis associated with pregnancy; 85 of these patients had been treated prior to conception, and 35 cases were incurred during pregnancy. Pregnancy itself was not associated with an unusual risk of relapse, though parturition was implicated in the recurrence of bacterial endocarditis in three patients. From the data given we cannot determine whether these recurrences represented new infections or were relapses of smoldering disease. However, it is significant that all three occurred among the 18 patients given no prophylactic antibiotics immediately before, during, or after labor. Among 102 patients receiving some prophylactic therapy, no recurrences or new cases of bacterial endocarditis were identified.

The choice of antibiotic regimens remains open. The tetracycline drugs apparently sterilize the parturient uterus far more effectively than does penicillin.[8] On the other hand, the objective of prophylaxis is prevention of bacteremia rather than reduction of uterine bacterial flora per se. For this purpose the bacteriocidal action of penicillin should prove advantageous. Since treatment of established enterococcic endocarditis usually requires streptomycin as well as large doses of penicillin, it might be reasonable to include the former in the prophylactic regimen. In any case, therapy should probably be initiated at the onset of labor and continued through the third postpartum day, as is recommended in other procedures associated with a hazard of bacteremia, and maximal antibiotic levels should be achieved shortly after delivery is completed.

Summary

From 202 blood samples obtained immediately after the third stage of labor and on the first postpartum day in 101 patients, only two potential pathogens, an alpha-hemolytic streptococcus and a coagulase-positive staphylococcus (micrococcus) were cultured. Postpartum bacteremia is probably an infrequent occurrence. The two positive results obtained and the accumulated clinical experience, however, amply justify the prophylactic use of antibiotics to prevent subacute bacterial endocarditis in susceptible patients during and immediately after labor.

ASSOCIATION OF SPECIFIC OVERT BEHAVIOR PATTERN WITH BLOOD AND CARDIOVASCULAR FINDINGS

BLOOD CHOLESTEROL LEVEL, BLOOD CLOTTING TIME, INCIDENCE OF ARCUS SENILIS, AND CLINICAL CORONARY ARTERY DISEASE

Meyer Friedman, M.D.
and
Ray H. Rosenman, M.D., San Francisco

Three groups of men, selected solely according to the behavior pattern which they habitually manifested in their work, were compared with respect to their serum cholesterol levels, clotting times, presence of clinical coronary disease, and presence of arcus senilis. A group (A) of 83 men were chosen as manifesting an intense, sustained drive for achievement and as being continually involved in competition and deadlines, both at work and in their avocations. In this group the serum cholesterol level, the frequency of arcus senilis, and the incidence of coronary artery disease were much higher than in a group (B) of 83 men who manifested the opposite sort of behavior pattern and a group (C) of 46 unemployed blind men selected as manifesting a chronic state of insecurity and anxiety. Clinical coronary artery disease was seven times more frequent in group A than in group B or group C. Analysis of factors other than the overt behavior pattern described indicated that this pattern per se was largely responsible for the striking differences found.

We previously reported results of a survey in 209 lay executives and physicians of their opinion of major causes of clinical coronary heart disease.[1] The majority of both groups believed that a person's chronic exposure to emotional trauma resulting from excessive "drive," competition, meeting "deadlines," and economic frustration was the major cause.

Acting on this possible lead, we studied serum cholesterol levels and blood clotting times of owner accountants before, after, and during isolated intervals of exposure to environmental influences that induced this emotional trauma.[1] Accountants were selected because their daily business life is relatively free of chronic lack of time, competition, and the need for intensive drive, except for isolated intervals. The results indicated that, independent of changes in diet or physical activity, their exposure to a situation capable of provoking an emotional complex induced a marked rise in serum cholesterol level and acceleration of blood coagulation.

Therefore, we considered it important also to study people who were more or less continuously immersed in the same emotional complex that only occasionally involved the accountants. Such a group had to be selected with care and compared with a second group not similarly exposed. Moreover, it was considered advisable to investigate a third group of persons who were not exposed to the above specific type of emotional activities but who displayed obvious evidence of a different type of emotional disturbance, namely, chronic anxiety. The results are reported here.

Methods of Study

Formulation of Behavior Patterns.—In order to study the possible pathogenic propensities of a particular emotional complex, formulation was made of a specific overt behavior pattern (pattern A) that we believed either was associated with or actually induced abnormal changes in serum cholesterol level and blood clotting time. Our belief stemmed from the above studies as well as from our own clinical experiences with younger patients suffering from clinical coronary disease.

This overt behavior pattern was characterized as follows: (1) an intense, sustained drive to achieve self-selected but usually poorly defined goals, (2) profound inclination and eagerness to compete, (3) persistent desire for recognition and advancement, (4) continuous involvement in multiple and diverse functions constantly subject to time restrictions (deadlines), (5) habitual propensity to accelerate the rate of execution of many physical and mental functions, and (6) extraordinary mental and physical alertness.

A second overt behavior pattern (pattern B) then was formulated. Essentially the converse of pattern A, it was characterized by relative absence of drive, ambition, sense of urgency, desire to compete, or involvement in deadlines.

A third overt behavior pattern (pattern C) also was formulated, characterized by its similarity to pattern B but also including a chronic state of anxiety or insecurity.

From the Harold Brunn Institute, Mount Zion Hospital.

Read, in part, before the Annual Meeting and 31st Scientific Sessions of the American Heart Association, San Francisco, Oct. 26, 1958.

Selection of Three Study Groups.—In the selection of group A (overt behavior pattern A), the aid of certain laymen of various corporations, independent companies, and newspaper organizations was requested. The behavior pattern and the general nature of the study were explained, and they selected associates most closely fitting this pattern, regardless of position, health, or other factors. It was hoped that a relatively random group of people might thus be chosen exclusively on the basis of their adjudged overt behavior pattern. Moreover, such persons were selectees rather than volunteers. Over 96% of the men selected subsequently agreed to cooperate.

The subjects were selected from engineering, paper manufacturing, and aluminum corporations, newspaper organizations, advertising agencies, grocery chains, television stations, and other independent businesses. Since selection was made on the exhibition of a particular behavior pattern and not because of economic position, various types of executives and nonexecutives were included in this group. Thus, it should be stressed that this is a study concerned not with the position but with the overt behavior pattern of the subjects.

Eighty-three men comprised group A. Eighteen were aged 30-40 years; 43 were aged 40-50 years; and 22 were aged 50-60 years.

Since we intended the men in group B (overt behavior pattern B) to be closely similar to those in group A in relevant physical and physiological respects, and differing essentially only in their overt behavior pattern, they were not selected until the group A men had been interviewed. Again, various businessmen and labor union officials selected for us the men of this group. They were selected from an employees' union of a municipal government, a union of professional embalmers, and 12 accounting firms. The members of these latter firms, unlike those of our earlier study,[1] did not have proprietor or partner status and were studied in February, a month relatively free of occupational urgency for accountants.

Group B also consisted of 83 men. Twenty-nine were 30-40 years of age; 37 were between 40 and 50; and 17 were between 50 and 60.

The primary reason men of group C (overt behavior pattern C) exhibited little ambition, drive, or desire to compete was the presence of total blindness for 10 or more years and the lack of occupational deadlines because none was gainfully employed. Their behavior pattern differed from that of subjects in group B only in their exhibition of a chronic state of insecurity and anxiety, due not only to financial insecurity but to the constant hazards to their physical security incurred in daily living.

Forty-six unemployed blind men were selected for us. Twenty-one lived in an institution, and 25 lived in their own homes. Sixteen were 30-40 years of age; 13 were between 40 and 50; and 17 were between 50 and 60.

The Personal Interview.—Each of the 212 subjects was carefully interviewed concerning parental incidence of coronary artery disease, past and present illnesses, hours of work and sleep, smoking habits, physical activity of all types, and dietary habits.

Then the degree of development of his particular behavior pattern was assessed by one of us prior to any subsequent procedures. The men of groups A and B were subdivided depending on whether they appeared to exhibit a completely or only an incompletely developed overt behavior pattern. Thus, a person was adjudged as exhibiting completely developed behavior pattern A if he exhibited various signs we believed indicative of its presence, including excessively rapid body movements, tense facial and body musculature, explosive conversational intonations, hand or teeth clenching, excessive unconscious gesturing, and a general air of impatience, and if he admitted his sustained drive, competitiveness, and necessity to accelerate many activities and was aware of a chronic sense of urgency in daily living. If one or both of the latter were inconsequential, the subject was classified as exhibiting an incompletely developed behavior pattern.

Similarly, in classifying men of group B, if an individual sat relaxedly, moved slowly and calmly, exhibited no muscular tension, spoke slowly, rarely indulged in tense gestures, exhibited no impatience, and denied even moderate drive or ambition, shunned competition, avoided involvement in deadlines, and felt no sense of urgency, he was adjudged as having a completely developed behavior pattern.

The men of group C were not assessed this way because of a ubiquitous general air of resignation, worry, and hopelessness.

Survey of Dietary and Alcohol Ingestion.—The men of groups A and B were carefully instructed in the dietary diary system previously found so successful,[2] each recording daily for seven days his complete intake of food and alcohol. Individual anonymity (code numbers) was used to avoid possible reluctance to report alcohol ingestion.

The diets of men in group C were obtained in the institutionalized subjects by calculation of four weekly menus and in the remaining blind subjects by daily telephoning for seven days to determine their actual food consumption. Their average alcohol intake was obtained by direct questioning.

The dietary intakes were calculated by the chief dietitian of Mount Zion Hospital (Evelyn Piercy, B.S.), who was never informed of the identity of the dietary diaries.

Blood Studies and Cardiovascular Survey.—For determination of serum cholesterol level and blood coagulation time, each subject was bled once at 9:00-11:00 a. m. and the total serum cholesterol level analyzed in duplicate.[3] The blood coagulation time of each subject was determined according to our previously described method.[1]

Detection of early or even late clinical coronary disease usually requires elicitation of a typical history of infarction or angina pectoris and/or specific electrocardiographic abnormalities. Therefore, each subject was questioned about possible rheumatic, congenital, hypertensive, or other heart disease, and then a careful history of possible infarction or angina pectoris was taken. A diagnosis of angina pectoris was entertained only if the subject had acute episodes of substernal pain with or without typical radiation, which probably could not be explained by any extracardiac ailment, if such episodes primarily occurred after exercise or emotional distress and were rapidly relieved by rest and/or nitroglycerine.

A standard 12-lead electrocardiogram was also obtained and considered diagnostic of coronary disease only if there were characteristically abnormal T waves, not ascribable to any known extracardiac cause, or diagnostic pattern of healed infarction. The tracings were interpreted, without identification, by one of us (R. H. R.) and again by an electrocardiographer not involved in this study. Except in one instance there was complete agreement in the two series of interpretations.

We also determined the incidence of arcus senilis in the men of groups A and B by meticulous gross inspection with use of frontal and lateral flashlight illumination of the eye.

Results—General Characteristics

Group A.—As table 1 indicates, the majority of the 83 subjects in group A were adjudged as exhibiting behavior pattern A in its fully developed form. These men appeared to be "doers," capable of accomplishing their particular functions, whether these had to do with heavy construction projects, running newspapers, organizing and executing advertising campaigns, merchandising foods and beverages, or manufacturing and distributing paper products throughout the nation. Nevertheless, it was apparent that they were chronically harassed by their various commitments, ambitions, and drives. It is an oversimplification to state that their key area of harassment and major source of frustration appeared to be the seeming paucity of time itself, due to the per se disparity that existed between the things they wished or felt impelled to do and the time available for such actions.

Findings in Group A°

Dietary Data											
Total Calories	Protein	Carbohydrates	Fat	Animal Fat	Fat, % of Total Calorie Intake	Voluntary Diet Restriction, %	Positive Parental History, %	Arcus Senilis, %	Clinical Coronary Disease, %	Clotting Time, Minutes	Serum Cholesterol Level, Mg./100 Ml.
2,007	342	760	905	653	45.1	18	36	7	18	6.6 (±0.2)	240 (±8.7)
1,937	329	672	936	690	48.3	56	39	43	32	6.8 (±0.12)	263 (±8.1)
2,152	384	804	964	719	44.8	63	33	66	50	7.2 (±0.18)	259 (±7.4)
2,011 (±59)	348 (±12.4)	728 (±28.)	935 (±32)	691 (±27.)	46.5 (±0.7)	50	37	42	34	6.8 (±0.09)	257 (±4.8)
2,428	325	902	1,201	747	49.5	0	25	0	0	7.4 (±0.30)	219 (±11.1)
2,189	383	895	911	623	41.6	50	43	16	0	7.3 (±0.35)	251 (±12.2)
2,097	421	763	913	726	43.5	50	25	50	0	7.1 (±0.32)	226 (±14.2)
2,223 (±109)	381 (±47.0)	864 (±31.2)	978 (±31.6)	684 (±38.2)	44.0 (±1.5)	36	33	21	0	7.3 (±0.28)	235 (±8.3)
2,049 (±58)	354 (±13.0)	751 (±26.)	944 (±28.)	690 (±23)	46.1 (±0.6)	48	36	38	28	6.9 (±0.11)	253 (±4.3)

The second most characteristic feature of these men was their eagerness to compete not only in daily vocational business activities but also in their avocational pursuits. Closely aligned was their admitted eagerness also to win in all such activities.

Finally, it was noted that men 40-50 years old predominated in this group, apparently due to the fact that, in the industries selected, it is such men who are most frequently observed by their associates and superiors to exhibit the characteristic traits of behavior pattern A. This is perhaps so because, in this decade, men displaying this behavior pattern will have attained a position wherein these traits may be more readily displayed and observed. Conversely, the smaller number of men aged 50-60 years was probably due to their relative scarcity in the more active, competitive divisions of various companies and businesses.

Group B.—Despite preliminary screening of various groups of men and conscientious efforts of our lay selectors, not all of the 83 men selected for us as exhibiting overt behavior pattern B were judged by us as displaying this pattern in its fully developed form. As table 2 shows, almost half of the men between 30 and 50 years of age were not adjudged by us as exhibiting a behavior pattern completely the exact converse of pattern A. As in the men of group A, obvious signs of severe neurosis were not often observed by us, although they generally were more excited about the studies than the men of group A, due partly to the fact that annual medical examinations were the custom with men of group A and rather the exception with men of group B. Although they were more excited or apprehensive about our studies, it was obvious to the trained observer that the external behavior of those exhibiting completely developed pattern B was totally and strikingly different from that of men in group A. The most striking difference was the relative or complete absence of the sense of time urgency so prevalent in group A.

In further sharp contrast, most men of group B were obviously more content with their respective lot in life and relatively uninterested in pursuing multiple goals or competitive activities. Few appeared really concerned with advancement, and most were far more involved with their families and avocational activities.

It is of interest and perhaps of importance that the men of group B exhibiting the incompletely developed behavior pattern were so assessed not because they had greater ambition or drive but primarily because they exhibited in some degree the sense of time urgency. But, while exhibiting this trait, they differed from men of group A in not being as consciously harassed by this sense of paucity of time.

TABLE 3.—*Summary of*

Av.	46	45	69	161	0	9 (±0.75)	8	61	12 (±2.7)	38 (±7.0)

* All figures in parentheses are standard errors of means.

As table 2 indicates, the greatest number of group B men were aged 40-50 years. This preponderance was purposely sought by us to provide age-paired controls for the men of group A.

Group C.—The unemployed, blind subjects in group C understandably exhibited typical signs of anxiety and insecurity. Half were learning a trade, reading, writing, and how to walk alone on city streets. These men exhibited worry and apprehension about their possible failures to earn a living. Their demeanor during our studies was neither the generally impatient one displayed by men of group A nor the somewhat apprehensive one shown by many men of group B. Previous physician contacts probably had conditioned them against fear of examinations or even venipuncture.

They were similar to group B men in not displaying any sense of time urgency, their speech, movements, and gestures being unhurried and devoid of overriding tension. None exhibited the slightest vestige of competitive drive or desire to excel. In summary, then, these subjects exhibited the behavior pattern found in men of group B, but with a universal overlay of understandable anxiety and insecurity.

Results—Subject Data

Age, Height, and Weight.—Tables 1, 2, and 3 indicate comparable age distribution in the three groups and the subdivisions of groups A and B. However, the preponderance of men 40-50 years old in groups A and B is not present in group C.

The average height of the men of group A was 2 in. (5.08 cm.) greater than that of men in group B or C, and their slightly greater average weight (4 lb. [1.8 kg.]) can be ascribed to this difference in height. The blind subjects, as a group, were less corpulent.

Work, Exercise, and Sleep Habits.—As tables 1, 2, and 3 indicate, group A men worked more hours per week (51 hours) than group B men (45 hours). (The subjects in group C were not gainfully employed.) This slight difference resulted from the men of group A beginning and ending their day's work earlier and later, respectively, than the men of group B.

Similarly (tables 1, 2, and 3), group A men were slightly more active physically (10 hours per week) than were group B men but not significantly more than the men in group C, who, surprisingly, indulged in much daily calisthenics and purposeful walking. Although certain studies have suggested that physical exercise may lower the serum cholesterol level, no such relationship was observed here (see figure). The sleep patterns of the three groups were similar.

Ingestion of Food, Tobacco, and Alcohol.—Satisfactory dietary records were obtained from 75 group A men, 76 group B men, and the 25 blind subjects who were not institutionalized. Tables 1, 2, and 3 indicate that the average dietary intakes of the men in groups A and B were approximately the same both qualitatively and quantitatively, although the average calorie intake of the blind subjects (group C) appeared to be somewhat greater. (It is believed that this is due to the fact that 21 of the 46 were fed a very liberal diet of 2,819 calories at the institution caring for them.) The percentage fat intake was comparable in all groups. Over 65% of ingested fat in each group was of animal origin. Not surprising to us[2] was the finding that the daily average calorie intake was far below that commonly assumed and that 48% of the men in group A and 31% of those in group B habitually restricted their food ingestion.

Although the percentage of group A men who smoked (67%) was not much greater than that in group B (56%) or group C (61%), the group A men smoked a daily average of 23 cigarettes, compared to 15 by group B men and 12 by group C men. Thus, group A men smoked more excessively than did men of the other two groups.

The average daily alcohol ingestion of group A men was somewhat higher than that of group B men, but the difference was not statistically significant (difference of means ÷ standard error of difference of means = 1.36). However, their average ingestion was much higher than that of the men of group C (tables 1, 2, and 3).

Parental Clinical Coronary Artery Disease.—Approximately 36% of group A men stated that either one or both parents suffered from clinical coronary artery disease. Twenty-seven per cent of group B men and 15% of group C men believed the disease present in one or both parents.

*Findings in Group C**

Dietary Data									
Total Calories	Protein	Carbohydrates	Fat	Animal Fat	Fat, % of Total Caloric Intake	Positive Parental History, %	Clinical Coronary Disease, %	Clotting Time, Minutes	Serum Cholesterol Level, Mg./100 Ml.
2,505	368	1,000	1,137	843	45.3	13	0	7.7 (±0.18)	207 (±7.8)
2,436	354	1,029	1,053	779	43.5	15	8	7.3 (±0.14)	228 (±6.6)
2,224	342	871	1,011	760	45.5	18	6	7.1 (±0.13)	226 (±8.5)
2,382 (±93)	354 (±18.6)	961 (±33)	1,067 (±61)	794 (±35.8)	44.9 (±0.8)	15	4	7.4 (±0.12)	220 (±5.2)

Serum Cholesterol Level.—The average serum cholesterol level of all the group A men was significantly higher (253 mg. per 100 ml.) than that of either group B men (215 mg. per 100 ml.) or group C men (220 mg. per 100 ml.). An even greater difference was observed by comparing the average serum cholesterol level of the men exhibiting completely developed behavior patterns in groups A, B, and C.

Blood Coagulation.—As tables 1, 2, and 3 indicate, the blind subjects in group C exhibited an average blood clotting time (7.4 minutes) that was significantly slower than that of group A men (6.9 minutes). However, the average clotting time of group B men (7.0 minutes) also was relatively rapid. Since a change in clotting time may occur very rapidly in response to various emotional stimuli,[4] it is quite possible that the acute apprehension observed in group B men at the time of the examination was itself responsible for their generally hastened clotting time. Nevertheless, when the average clotting time (6.8 minutes) of the men exhibiting fully developed pattern A was compared with that (7.2 minutes) of the men exhibiting fully developed pattern B, the difference was still significant. It was of interest, too, that the average clotting time was less than 7 minutes in 67% of the group A men, in 51% of group B men, and in only 20% of group C men.

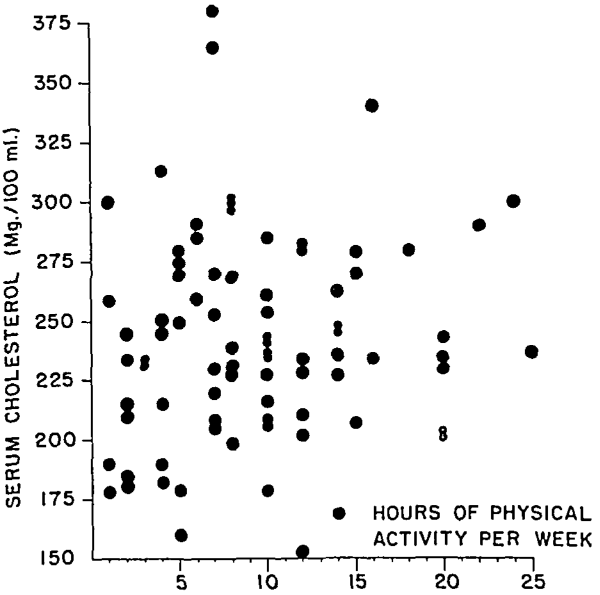
Arcus Senilis.—The difference in incidence of arcus senilis was striking (tables 1 and 2), being over three times greater in group A than in group B men. This discrepancy became five times as great when respective segments of each group exhibiting the completely developed patterns were compared. Parenthetically, it should be stated that no valid correlation was observed between the incidence of this ocular phenomenon and the level of serum cholesterol.

Results—Clinical Coronary Artery Disease

Incidence.—A marked disparity in the incidence of clinical coronary disease was found in the three groups of men selected at random and supposedly differing only in their particular overt behavior pattern. Thus (table 4), 23 group A men (28%) exhibited either clear-cut symptoms or definitive electrocardiographic signs of clinical coronary disease, findings noted in only 3 of the 83 men of group B and in only 2 of the 46 men of group C.

These results were even more striking when comparing the respective subgroups of A and B. Thus, all 23 cases of clinical coronary disease in group A were found in the men of subgroup A displaying the fully developed behavior pattern, whereas the 3 clinical instances in group B were observed in the subgroup displaying the incompletely developed pattern B.

The diagnosis of clinical coronary artery disease was made in 4 of the 23 subjects in group A by the history of typical angina, in 10 by characteristically abnormal electrocardiograms, and in 9 by a combination of history and electrocardiographic criteria. It is of interest that, of 8 of the 23 subjects with indisputable electrocardiographic evidence of healed myocardial infarction, only 4 were aware of having suffered a heart attack. These same 4 persons also were the only ones of the total of 23 who were aware of their clinical coronary disease. The remaining were completely unaware of its presence. Two of the three cases of clinical coronary disease in group B were diagnosed by electrocardiographic criteria and the third by a history of angina. One of the two cases in group C was diagnosed by history and electrocardiographic criteria and the second by electrocardiogram. Neither of the subjects in group B and only one in group C was aware of suffering from clinical heart disease.



Relationship of serum cholesterol level and exercise of men of all groups between 40 and 50 years of age.

Possible Correlation of Incidence with Other Factors.—The above findings should be a stimulus for further study, since they do not describe some biochemical deviant, having possible relevance to heart disease, but depict an overwhelming difference in heart disease incidence in groups of men selected initially only on the basis of observed differences in overt behavior patterns.

In table 4, the various data collected from subjects considered to have clinical coronary disease are assembled. Comparison of age, height, and weight of those with cardiac disease with those obtained from all subjects reveals that these factors cannot apparently be given pathogenic relevance to the question under study.

Similarly, the factors of sleep and exercise do not appear different in the 23 subjects with cardiac disease in group A. Their weekly period of working hours (52 hours) is not longer than that of all of the men of group A but is longer than that found in men of group B. That this longer period of daily work is, per se, the cause of the higher incidence of heart disease in men of group A seems unlikely, since the total national incidence of clinical coronary disease has risen over the past decades even though the number of working hours has declined. Furthermore, none of the 18 subjects in group B who had been working 50 or more hours per week exhibited clinical disease. The latter group includes a small number, but certainly if a group of 83 persons (group A) provides 23 cases of clinical disease because of long working hours, the factor(s) responsible might also be expected to produce at least one case in the 18 persons of group B also working a similar number of hours.

The dietary data indicate that the diet of men in group A, at each decade, did not differ from that of men in group B or C either in calorie intake or in the type of fat ingested. Furthermore (table 4), the men of group A with clinical heart disease who were unaware of its presence ingested quantitatively and qualitatively the same diet as that taken by other members of group A and by those of groups B and C. It seems clear that it is not the diet or any of its constituents which, acting alone and of itself, can be held responsible for the presence of so much coronary heart disease in group A men.

The greater tobacco consumption by group A men seems a possible cause of their high incidence of clinical disease, but closer inspection reveals that heavy cigarette smoking could not, per se, be responsible for the high incidence of heart disease in the men of group A. Thus, of 60 group A men smoking 10 or more cigarettes a day, 16 were found to have cardiac disease (27%), but of the 23 remaining Group A men who smoked 10 or fewer cigarettes daily, seven had cardiac disease (30%). Thus, as many light smokers or nonsmokers exhibited clinical disease as did the heavy smokers of group A. Moreover, there were 46 men of group B who smoked heavily, yet only 2 (4%) exhibited clinical coronary disease and only 1 of the 37 light smokers or nonsmokers of this group developed detectable coronary disease. The data suggest that excessive

* All figures in parentheses are standard errors of means.

smoking may be a characteristic of overt behavior pattern A but not a causal agent of the high incidence of cardiac disease found characteristic of this pattern.

Alcohol.—The average daily alcohol consumption of the 23 subjects with cardiac disease in group A and of the three in group B was higher than the average of their respective groups. Despite this, 12 of the 23 in group A did not drink or ingested less than the equivalent of 150 calories per day. Thus, of 44 group A men who drank little or none, 12 (27%) were found to have cardiac disease. The remaining 39 group A men who drank more included the remaining 11 with cardiac disease (28%). If the considerable ingestion of alcohol played a role in the pathogenesis of this disorder, one might expect a higher incidence of the disease in men belonging to a group given to heavy drinking. Like cigarettes, greater ingestion of alcohol in group A appears to be associated with the behavior pattern rather than of pathogenic consequence.

Parental Incidence of Coronary Artery Disease.—The apparently greater parental incidence of coronary disease in men chosen according to a prescribed psychological pattern might be blamed for their greater incidence of heart disease. However, the greater parental incidence could not be due to the behavior pattern of the men, but, rather, it is possible that these group A men had inherited some of their behavior pattern traits and it was the presence in their parents of these same traits that led to the latters' own greater incidence of cardiac disease. It was observed in a man with cardiac disease that, if his father also had suffered from coronary artery disease, the latter's personality was similar to his own. Contrariwise, in most instances where the father had not similarly suffered, the person with cardiac disease sharply differentiated his own personality from that of his father's.

Total Calories	Protein	Carbohydrates	Fat	Animal Fat	Fat, % of Total Calorie Intake	Positive Parental History, %	Arcus Senilis, %	History Alone, %	ECG Alone, %	Both, %	Serum Cholesterol Level, Mg./100 Ml.	Clotting Time, Minutes
1,840 (±75)	320 (±14.2)	659 (±32)	861 (±37.2)	621 (±31)	46.8 (±1.8)	35	65	17	43	40	251 (±14.2)	6.8 (±0.14)
1,918	296	682	940	708	49.0	0	0	33	66	0	237	6.7
2,819	409	1,130	1,280	984	45.5	50	...	0	50	50	232	7.8

The data also revealed that of the 30 group A men having a positive parental history, only 8 (27%) had heart disease and of 53 men without a parental history 15 (28%) had heart disease. None of the 23 group B men with positive parental history exhibited clinical heart disease.

The data fail to incriminate differences in positive parental history between group A and B as being responsible for their markedly different incidence if clinical coronary artery disease.

Serum Cholesterol Level.—The unmistakably different average serum cholesterol level in group A and group B men might be considered responsible for the greater incidence of clinical coronary artery disease in group A. However, the average serum cholesterol level of the 19 subjects with cardiac disease in group A (the four men aware of their disorder and possibly on special diet were not included) is not significantly different from that of the total group (table 4). Second, again omitting the four with known cardiac disease, among 36 group A men with a serum cholesterol level exceeding 250 mg. per 100 ml., 10 (26%) exhibited clinical coronary disease and, of 43 having a serum cholesterol level below 250 mg. per 100 ml., 10 (23%) exhibited clinical coronary disease. Moreover, of the 14 group B men having a serum cholesterol level exceeding 250 mg. per 100 ml., only 1 exhibited clinical coronary disease. These results suggest that, as in greater working hours, smoking, and ingestion of alcohol, a comparatively higher serum cholesterol level also is an accompaniment of overt behavior pattern A rather than a cause of the higher incidence of clinical disease.

Blood Coagulation.—Although the average clotting time (6.8 minutes) of the 23 subjects with cardiac disease in group A was relatively rapid, it was similar to that of the other men in this group and only slightly more rapid than that of the subjects in group B. The data do not permit attributing the high incidence of cardiac disease in group A to an alteration in the clotting time.

However, it is likely that the incidence of thrombotic complication must have been far greater in group A than in the other groups, since the emergence of clinical coronary artery disease so often follows a thrombotic complication in an atherosclerotic coronary artery.[2] We, therefore, do not feel justified to dismiss the possible role of a chronically or episodically hastened clotting time in the pathogenesis of clinical coronary artery disease, despite the present failure to demonstrate its relevance in this regard.

Comment

The preceding observations demonstrate that men exhibiting a specific overt behavior pattern (type A) also exhibit higher serum cholesterol levels, a more rapid clotting time, a greater incidence of arcus senilis, and a far greater incidence of clinical coronary artery disease than men exhibiting converse behavioral traits or a simple anxiety state. These differences, moreover, cannot be ascribed to differences in exercise, calorie or fat intake, alcohol, or cigarettes.

The failure to detect any extraneous factor that might have induced these differences suggests that the behavior pattern itself is responsible for the changes in blood cholesterol level and cornea and coronary vasculature. Certainly, changes in blood cholesterol level and clotting time occurring in accountants exposed to one element of this behavior pattern (i. e., the involvement in deadlines), suggest that the chronic exhibition of this behavior pattern indeed can induce a sustained rise in serum cholesterol level and acceleration of blood clotting time. Groover,[5] Hammarsten and associates,[6] and Wertlake and co-workers[7] have reported similar striking elevations of the serum cholesterol level after exposure to emotional factors similar to those at play in behavior pattern A.

In view of the present data it is significant that, in studying patients with clinical coronary disease, many of them already have been found[8] to exhibit many of the qualities making up the behavior pattern under discussion. Thus, although Gertler and others,[9] in their study of 100 young patients with coronary disease, and later Miles and associates,[10] studying the same men, did not find any significant differences in their personalities, careful scrutiny of their data reveals that the majority of these 100 men actually did exhibit many of the qualities characterizing behavior pattern A. For example, their patients exhibited several times the proficiency of their controls in their high school athletic careers and were even described as "hard-driving and goal-directed."[9] A mesomorphic constitution, as these authors suggest, might explain their athletic superiority in high school but not the drive, ambition, and competitive spirit that were further needed to obtain athletic awards and the higher civil positions successfully obtained by these men in later life. It seems to us more fruitful to incriminate the cast of a personality than the contours made by muscle and bone.

The present study again points out, as Yudkin,[11] Page and associates,[12] and Yerushalmy and Hilleboe[13] previously have done, the dangers of attributing to dietary ingestion of fat alone a too preponderant role in the pathogenesis of clinical coronary artery disease. Thus, the average serum cholesterol levels of the men of groups B and C were as low, at all ages, as those of subjects[14] ingesting only half as much fat. Indeed, the lower serum cholesterol level and the markedly lower incidences of arcus senilis and clinical coronary artery disease in the men of group B, despite the equivalence of their calorie and fat intake with that of the men of group A, clearly indicate the presence of additional, perhaps far more important, factors at work in the pathogenesis of the disease.

Despite the importance of the behavior pattern itself, we believe that chronic ingestion of a high-fat diet must play an important role in the causation of clinical coronary artery disease. Our conviction is based on the simple fact that feeding excessive fat to various laboratory animals frequently induces atherosclerosis. However, the lethalness of a high fat intake for man apparently depends on an interplay with other important factors. Unfortunately, neither the mechanism by which a high fat intake experimentally increases the serum cholesterol level and induces atherosclerosis nor the mechanism by which a behavior pattern might effect the same phenomena is known. Indeed, even the mechanism responsible for control of the "normal" serum cholesterol level remains unknown. Until such mechanism can be discovered assumptions based on data other than those obtained from closely controlled studies must be viewed with extreme reserve. The investigator, moreover, must be willing to acknowledge the possible presence of pathogenic factors which cannot be measured by those instruments or techniques now available to him.

It should again be emphasized that this is a study of men exhibiting different behavior patterns and not a study of the effects of any particular type of vocational position or socioeconomic status. The recent observations of Pell and D'Alonzo[15] and Lee and Schneider[16] indicate clearly enough that the responsibility or the socioeconomic importance of the subject's position does not govern the incidence of clinical coronary disease. We suspect that a behavior pattern is the result of a specific reaction of the individual to his particular environment, in which case the pattern might be altered by a change either in the person's reaction or in his environment. In this latter respect, it is of interest that, in our previous study of accountants,[1] their behavior pattern and serum cholesterol levels (in April, during their deadline period) resembled those of men of group A but, in February (in the absence of a deadline), resembled those of men of group B.

Whatever is responsible for the behavior pattern A herein described, certainly it is neither confined to nor perhaps even more common in any particular echelon of corporate or industrial life. Actually, as Stewart[17] has emphasized, the emergence of this behavior pattern now seems to be an ubiquitous and status-transcending phenomenon in our Western society. It should be emphasized, too, that the stresses of this same society are of a variety never previously witnessed in any previous age of society, as the distinguished historians, Toynbee ("A study of History") and De Jouvenel ("Sovereignty") have pointed out. To confuse the identity and effects of these stresses with those of simple neuroses is to err, as the results of this paper demonstrate.

It appears almost mandatory in a study of this kind that the assessment of various behavior patterns actually be done by the investigators themselves, even though this decreases the number of subjects that can be studied. On the other hand, study of even thousands of subjects cannot eliminate the possible error that is introduced if such a study contains two or more variables. Thus, if only one variable is recognized and thus accorded erroneous validity, then the use of thousands may only multiply the seriousness of the error.

Summary

The possible effect of socioeconomic pressure and stress in the pathogenesis of clinical coronary artery disease was studied in men exhibiting three different overt behavior patterns. Men of group A exhibited a behavior pattern primarily characterized by intense ambition, competitive "drive," constant preoccupation with occupational "deadlines," and a sense of time urgency and the men of group B, a converse behavior pattern. Men of group C exhibited a behavior pattern essentially similar to that exhibited by men of group B, but with the added elements of a chronic anxiety state.

The total calorie and fat intake and the amount of physical activity were approximately the same in all groups, and the age, height, and weight of men in the three groups were comparable. Despite these similarities, the average serum cholesterol level was much higher in group A than in the other two groups. A hastening of blood clotting time was not observed in all men of group A, but only in those exhibiting the most fully developed form of the behavior pattern.

Far more striking, however, was the startling difference in incidence both of clinical coronary artery disease and of arcus senilis. Thus clinical coronary artery disease was seven times more frequent, and arcus senilis was over three times more frequently present in the men of group A than in those of group B or group C.

The possible role of cigarette smoking, exercise, working hours, alcohol ingestion, and heredity was studied in the pathogenesis of the cases of clinical coronary heart disease, but none, per se, appeared to have pathogenic relevance.

The results obtained in this study strongly suggest that the behavior pattern exhibited by the men of group A was of itself largely responsible not only for their higher serum cholesterol and possible hastening of clotting time but also for their markedly increased incidence of both clinical coronary artery disease and arcus senilis.

1600 Divisadero St. (15) (Dr. Rosenman).

This study was supported, in part, by grants from the Alameda County Heart Association and the Contra Costa County Heart Association.

Erika de Long, M.D., Vernice Carroll, Clarence Omoto, B.S., Warren Hayashi, B.S., John Proctor, B.A., Malcolm Smith, B.A., Betty Tsai, M.S., Donna Cary, B.S., Lillian Daniels, B.A., and Vivian Anderson of the Harold Brunn Institute furnished technical assistance in this study and Evelyn Piercy, B.S., Chief Dietician, Mount Zion Hospital, analyzed the dietary records. Paul M. Aggeler, M.D., assisted in blood coagulation studies.

The authors also wish to express their gratitude to the following individuals whose aid and participation made this study possible: Jerome Rosefield, vice-president (retired), Best Foods, Inc.; Walter Guild, president, Guild, Bascom and Bonfigli; Harold Zellerbach, chairman of the executive committee, Crown Zellerbach Corporation; E. A. Paul, director of industrial relations, Crown Zellerbach Corporation; William Pomeroy, executive vice-president, J. H. Pomeroy & Company, Inc.; Norris Nash, vice-president, Kaiser Industries Corporation; Clifford Keene, M.D., director of medical relations, Kaiser Industries Corporation; John H. Beatty, M.D., physician, Kaiser Industries Corporation; Leon Miller, president, Littleman Stores; Arthur Becker, executive vice-president, Littleman Stores; Joseph Cauthorn, president, the San Francisco *News*; Milton Silverman, science editor, San Francisco *Chronicle*; John Allen; science writer, San Francisco *Examiner*; Jack Ryan, science writer, Oakland *Tribune*; Harold Kehoe, director, Alameda County Welfare Commission; Allen Jenkins, administrator, Oakland Orientation Center for the Blind; Leora Ricketts, supervising social worker, Alameda County Welfare Commission; Audrey Calder, director, campaign and public relations, Alameda County Heart Association; volunteers of Alameda County Heart Association; George W. Johns, secretary, San Francisco Labor Council; Hansel Harter, assistant manager, N. Gray & Co., Funeral Service; John Jeffery, business representative, San Francisco City and County Employees no. 400; Edward Voss, vice-president, Annabelle Candy Company, Inc.; and Sanborn Company, San Francisco, for loan of electrocardiographic equipment.

PROLONGED ADMINISTRATION OF CHLORPROMAZINE (THORAZINE) HYDROCHLORIDE

CLINICAL AND LABORATORY SURVEY OF FIFTY PATIENTS

Frank J. Ayd Jr., M.D., Baltimore

Since chlorpromazine strikingly improves the adjustment of many psychiatric patients without being truly curative, administration in many cases must be continued for years. In order to detect possible adverse effects of such prolonged medication, a study was made in 50 patients who took it for two to four years. The total amounts taken by individual patients ranged from 54 to 1,078 Gm. All patients gained weight. No evidence of renal or hepatic dysfunction was found. Amenorrhea occurred in two-fifths of the women, but sometimes menstruation was resumed without interruption or reduction of the dosage. In some patients the white blood cell count dropped as low as 3,000 per cubic millimeter of blood; but it was not necessary to interrupt the medication, because the counts returned to normal while chlorpromazine therapy continued. Three patients manifested photosensitization each year from May to October but were desensitized by repeated limited exposures to the sun. Chlorpromazine enabled these patients to remain outside of the hospital, to work, and to be reasonably comfortable in spite of the persistence of their basic illness.

Shortly after the introduction of chlorpromazine (Thorazine) hydrochloride, it was realized that this drug could cause jaundice and agranulocytosis and that some psychiatric patients would require it indefinitely. Consequently, concern was expressed about the hazards of prolonged chlorpromazine therapy, particularly its effects on the liver and the hematopoietic system. In studying this important problem, a complete laboratory survey was made on patients who had taken chlorpromazine from two to four years. The results of this laboratory evaluation and pertinent clinical observations are the basis of this report.

This group consisted of 31 women and 19 men, aged 12 to 70. In this group were 3 men under 20, 1 man and 8 women aged 20 to 29, 12 men and 13 women aged 30 to 39, 3 men and 4 women aged 40 to 49, 3 women aged 50 to 59, 2 women aged 60 to 69, and 1 woman over 70. Diagnostically, they were categorized as follows: schizophrenic–paranoid 10, catatonic 2, hebephrenic 1, simple 1, unclassified 9, chronic hypomanic 2, chronic agitated depression 1, psychoneurosis or anxiety state 9, obsessive–compulsive neurosis 8, pseudoneurotic schizophrenia 4, and hyperkinetic brain-injured child 3. Prior to taking chlorpromazine they had been ill from 1 to 20 years and had not responded to previ-

Chief of Psychiatry, Franklin Square Hospital.

ous psychiatric treatment, including shock therapy and psychosurgery. At the start of chlorpromazine therapy 18 were hospitalized and 32 were at home. All were considered totally incapacitated, and none had a good prognosis for recovery.

Table 1 gives the daily dosage range, the total dosage, and the duration of treatment. This reveals that the dosage requirements of patients within the same diagnostic category varied markedly. In some instances neurotics required higher doses than psychotics to obtain and maintain improvement. Thus, it is evident that chlorpromazine is used to control symptoms and not to treat a psychosis or neurosis. Because of the difference in dosage requirements, there is a corresponding variation in the total dosage taken by the patients. Minimum total dosage was 54,000 mg.; the maximum was 1,078,000 mg. Either exceeds that usually taken by patients treated with chlorpromazine. The dosage was large enough that it is reasonable to assume that any deleterious effects should be detectable.

TABLE 1.—*Dosage and Duration of Treatment with Chlorpromazine*

Case No.	Sex	Age	Diagnosis	Daily Dosage Range	Total Dosage	Duration of Treatment, Mo.
1	F	32	Pseudoneurotic schizophrenia	100-1,800 mg.	645,000	47
2	M	39	Pseudoneurotic schizophrenia	50-300 mg.	201,000	47

Laboratory Investigation

Prior to, at repeated intervals during, and at the beginning of this survey, each patient had a urinalysis, hematological studies (red blood cell count, hemoglobin level determination, white blood cell count, and differential count), and liver function tests (cephalin flocculation, direct and indirect bilirubin, alkaline phosphatase, and, occasionally, thymol turbidity). Pretreatment and survey urinalysis were all within the range of normal variations. Urine bilirubin determination was negative in all cases.

Results of hematological studies are given in table 2. Repeated white blood cell counts and differential counts during therapy disclosed fluctuations in the total white blood cell count and the total number of neutrophils. In some patients, the white blood cell count dropped as low as 3,000, with 30 neutrophils and with a return to normal as therapy with chlorpromazine was continued. It is not necessary to discontinue the therapy when the white blood cell count and neutrophil count begin to fall. In such instances the physician should rely on his clinical judgment, in addition to the laboratory studies, to determine his course of action.

Table 3 presents the liver function studies. Only the cephalin flocculation test showed changes in some patients. A summary of these changes is given in table 4. The results are not significant (table 5). Whether they are due to chlorpromazine or other causes is unknown. In two patients there was a history of virus infection with liver involvement prior to chlorpromazine therapy and of a chronic alcohol problem with periodic heavy drinking while taking chlorpromazine. In these two cases it was felt that factors other than chlorpromazine therapy could be responsible for the changes in the cephalin flocculation tests.

All major laboratory test results were analyzed for any significant change which might have occurred. The mechanism employed was the Student's *t* test (table 5). The values of *t* are far below those which would indicate a significant difference between the pretreatment test results and survey test results.

Clinical Observations

Body Weight.—One of the most constant endocrine actions of chlorpromazine is that which affects the weight of patients receiving it. Every patient gained from 20 to 54 lb. (9.1 to 24.5 kg.), the average being 35 lb. (15.9 kg.), irrespective of the pretreatment weight. Four patients gained 20 to 25 lb. (9.1 to 11.3 kg.); 8, 25 to 30 lb. (11.3 to 13.6 kg.); 15, 30 to 35 lb. (13.6 to 15.9 kg.); 13, 35 to 40 lb. (15.9 to 18.1 kg.); 8, 40 to 45 (18.1 to 20.4 kg.); 1, 45 to 50 lb. (20.4 to 22.7 kg.); and 1, 50 to 54 lb. (22.7 to 24.5 kg.).

In the first four months of treatment patients gained weight rapidly, usually two-thirds of their total weight increase. In the next 6 to 10 months, they gradually added the remaining one-third of their total weight gain. Thereafter, their weight remained relatively constant. If dosage was lowered or the drug therapy stopped, a gradual weight loss followed but weight remained well above the pretreatment level. The photographs in the illustration show the considerable weight change in one patient.

Menstrual Changes.—The menstrual changes observed were disruption of rhythm, menorrhagia, hypermenorrhea, hypomenorrhea, and amenorrhea. The menstrual variations usually began after two weeks of therapy. In some patients the drug produced early onset of menses; in others it was delayed. Amenorrhea occurred in two-fifths of the women receiving 500 mg. or more daily. The higher the dosage used the more likely was amenorrhea to occur. As the dosage was lowered, the menses

returned. When amenorrhea happened, it varied from three months to two years, the average being six months.

Photosensitivity.—Three patients were photosensitive. There was no relation between this sensitivity and the dosage of chlorpromazine. This reaction was seasonal, occurring from May to October, when the patients were exposed to the summer sun. Repeated limited exposure to the sun desensitized the patients, but the reaction recurred each year.

Comment

None of the patients in this study have recovered from their basic illness, although all have shown symptomatic improvement. The 18 hospitalized patients are now at home; 4 are gainfully employed, and 7 have resumed responsibility for their household duties. Of the 32 nonhospitalized patients, 11 have returned to work and 14 are helping with the household work. It is certain that without chlorpromazine therapy most of these patients would have gradually deteriorated and would now be hospitalized. Instead, chlorpromazine therapy has enabled them to remain outside of a hospital, to work, and to be reasonably comfortable in spite of the persistence of their basic illness.

TABLE 5.—*Comparison of Pretreatment and Survey Laboratory Results in Fifty Patients*

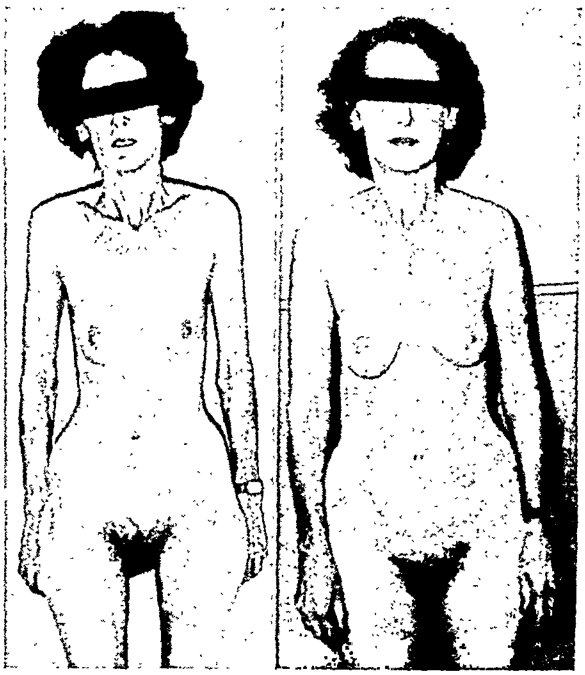
	Mean		
Test Results	Pretreatment	Survey	Value of t*
Red blood cell count, million/cu. mm.	4.7	4.8	0.017
White blood cell count, per cu. mm.	7,600	8,300	0.27
Polymorphonuclear cells, total	4,720	5,470	0.30
Cephalin flocculation			
24-hr. reading	0.03	0.29	0.49
48-hr. reading	0.17	0.52	0.45
Bilirubin, indirect	0.51	0.57	0.94
Alkaline phosphatase level, units per 100 cc.†	2.16	2.32	0.15
Thymol turbidity units‡	2.4	2.8	0.40

* Determined in Student's *t* test.
† Alkaline phosphatase level was determined in only 49 patients.
‡ Thymol turbidity determination was made in only nine patients.

These patients have continued on maintenance therapy with chlorpromazine because each time an effort was made to withdraw the drug there was a resurgence of former symptoms. Even the maintenance dose has had to be flexible. For some patients it has been necessary occasionally to increase their dosage temporarily when they encountered more environmental stress than usual.

Summary and Conclusions

Chlorpromazine (Thorazine) hydrochloride has been administered from two to four years to 50 psychiatric patients who had not benefited from previous treatment and who had a poor prognosis. These patients took from 54,000 to 1,078,000 mg. A comparison of their pretreatment and survey urinalysis and hematological and liver function studies did not reveal any significant changes. Every patient gained from 20 to 54 lb. (9.1 to 24.5 kg.), usually during the first year of chlorpromazine therapy, after which the weight remained constant. Amenorrhea occurred in two-fifths of the women. Its duration varied with the dosage of chlorpromazine. Lowering the dosage restored normal menses if normality did not return of itself. Photosensitive reactions occurred in the same three patients each year.



Weight change in patient on chlorpromazine therapy. *Left,* pretreatment weight, 80 lb. (36.3 kg.). *Right,* weight 90 days later, 109.5 lb. (49.6 kg.), after therapy with 125 mg. of chlorpromazine daily. Weight at end of one year was 115 lb. (52.1 kg.) and during next three years varied from 110 to 118 lb. (49.9 to 53.5 kg.).

It is concluded that chlorpromazine can be administered for prolonged periods, even in large doses, without the risk of harmful effects on the blood, liver, or kidneys. Prolonged therapy does not cure. It enables patients to remain outside of the hospital, to work, and to be reasonably comfortable in spite of the persistence of their basic illness.

DIFFUSE PULMONARY SCHISTOSOMIASIS

REPORT OF TWO CASES PROVED BY LUNG BIOPSY

Major Joel H. Richert
and
Major Richard B. Krakaur, (MC), U. S. Army

Two patients with signs and symptoms of chronic pulmonary disease were hospitalized because of the suspicion of tuberculosis. In one a lung biopsy specimen obtained at exploratory thoracotomy was found to contain lesions characteristic of pulmonary schistosomiasis, and ova of Schistosoma mansoni were identified. In the other the ova of S. mansoni were first found in the feces; later the characteristic ova were also found in pseudotubercules in specimens of lung tissue obtained by wedge biopsy. The first patient was treated with a total of 90 cc. of stibophen (Fuadin) injected intramuscularly over a period of 20 days, and the disease was arrested. The other improved after two courses consisting altogether of 95 cc. of stibophen; although he continued to complain of respiratory symptoms he returned to duty. Both had lived in Puerto Rico before entering the U. S. Army.

Pulmonary schistosomiasis was first described by Belleli,[1] in 1885, and since then other authors have described in detail the clinical and pathological features. Since schistosomiasis is not endemic to the United States, physicians in this country are not likely to include it in the differential diagnosis of lung diseases. In recent years large numbers of people have migrated to the United States from Puerto Rico, where the disease is endemic. A number of these persons can be expected to have pulmonary schistosomiasis, which is easily confused with tuberculosis, histoplasmosis, sarcoidosis, pneumonoconiosis, or eosinophilic granuloma.

Report of Cases

Case 1.—A 22-year-old male Puerto Rican soldier was admitted to the tuberculosis section of Fitzsimons Army Hospital on Feb. 23, 1954, because of diffuse pulmonary infiltrates.

He had lived in Puerto Rico until he entered the U. S. Army in March, 1953. In April, 1953, he was transferred to the United States where he has since remained, residing in Kansas, Texas, Louisiana, Colorado, and Illinois. Before entering the Army he was employed as a steelworker for two years. There is no record of how or when he became infected with schistosomes. His medical history was unremarkable except for an appendectomy at the age of 19. Three months prior to hospitalization he developed a cough productive of brownish-black sputum. This was most prominent at night and was only slightly improved by cough medication. No diagnostic studies were done until January, 1954, at which time he complained of some weakness but denied having hemoptysis, night sweats, or chest pain. A chest roentgenogram showed diffuse infiltrates and he was hospitalized because of the suspicion of tuberculosis.

On the physical examination given at admission he appeared well nourished and in no distress. Blood pressure was 142/90 mm. Hg, respirations 24 per minute. There was no clubbing of fingers or toes. Scattered inspiratory rales were audible over both lungs. The examination results were otherwise normal. Results of laboratory studies were as follows: serologic test for syphilis, negative; urinalysis, normal; hemoglobin level, 16.5 Gm. per 100 cc.; white blood cell count, 11,000 per cubic millimeter with neutrophils, 58%; lymphocytes, 32%; and eosinophils, 10%. Subsequently, the eosinophil counts ranged between 5 and 9%. The total serum protein level was 8.2 Gm. per 100 cc., with albumin, 3.7 Gm. and globulin, 4.5 Gm. Liver function studies done on separate occasions showed sulfobromophthalein (Bromsulphalein) retentions of 6.2, 3.0, and 8.0%. The thymol turbidity and cephalin flocculation were normal on each determination. The second-strength purified protein derivative (PPD) skin test gave a positive result. Results of coccidioidin and histoplasmin skin tests were negative in all dilutions including 1:10. Serologic tests for histoplasmosis, blastomycosis, and coccidioidomycosis obtained on March 3 and April 9 all gave negative results, except that on the first determination the result of the collodion agglutination test for histoplasmosis was positive in a dilution of 1:40. Cultures of gastric and bronchial washings were negative for Mycobacterium tuberculosis and fungi. A bone marrow culture was negative for Histoplasma capsulatum. Stool specimens initially contained ova of Schistosoma mansoni and hookworm and the rhabditiform larvae of Strongyloides stercoralis.

Pulmonary function studies on April 29th yielded the following results: Vital capacity, 2,600 cc. or 61% of the predicted normal; one-second vital capacity 2,200 cc. or 85% of the observed; maximum breathing capacity, 75 liters per minute or 53% of the predicted normal.

Roentgenograms of the chest (fig. 1) showed diffuse miliary infiltrations involving all lobes of both lungs, with scattered coalescent nodules measuring up to 5 mm. in diameter. In addition, there was a reticular pattern of increased lung markings. Serial roentgenograms throughout the period of hospitalization remained stable. A miniature film made in March, 1953, showed normal findings.

Bronchoscopy revealed a mild, diffuse hyperemia and edema of the tracheobronchial tree. A needle biopsy of the liver was performed and on microscopic examination the liver architecture was essentially normal with only a small focal area of fibrosis. A lung biopsy specimen, obtained at exploratory thoracotomy on May 18, contained lesions characteristic of pulmonary schistosomiasis. Frequent large

---

From the departments of medicine and pathology, Fitzsimons Army Hospital, Denver.

ocal granulomatous areas were present, composed of fibroblasts, histiocytes, eosinophils, and occasional lymphocytes and plasma cells. In these areas were seen arteries with destruction of the muscular coat and varying degrees of obliterative endarteritis. No angiomatoid formation was found. Ova were not observed within these granulomas, but they were seen within organized pseudotubercles located in nearby alveolar spaces (fig. 2). The remainder of the pulmonary parenchyma appeared normal.

This patient presented a perplexing diagnostic problem; after tuberculosis was excluded as a diagnostic possibility, histoplasmosis and sarcoidosis were seriously considered. When ova of S. mansoni were found in the lung biopsy specimen as well as the stools all of the confusing features could be easily explained. At operation the surgeon palpated firm nodules measuring 2 to 6 mm. throughout the entire lung. There were no postoperative complications.

The patient was treated with a total of 90 cc. of stibophen (Fuadin) injected intramuscularly between June 21 and July 10. This produced some nausea, anorexia, and vomiting but did not necessitate discontinuance of the therapy. Hexylresorcinol was given for the hookworm and gentian violet for the strongyloides infections. At the completion of treatment his stools no longer contained ova and parasites. He returned to duty in August, 1954, and was subsequently discharged from the Army.

A follow-up evaluation was accomplished at the Veterans Administration West Side Hospital, Chicago, during December, 1955, and January, 1956. At that time the patient complained of shortness of breath on exertion but denied any other pulmonary symptoms. No significant physical abnormalities were found. The routine laboratory studies gave normal results, except for 9% eosinophils in a peripheral blood smear. A total circulating eosinophil count was 482 per cubic millimeter. Stool examinations revealed ova of hookworm but none of S. mansoni. A sulfobromophthalein test showed 3.5% retention. The total serum protein level was 7.8 Gm. per 100 cc., with albumin, 4.7 Gm., and globulin, 3.1 Gm. The vital capacity was 2,800 cc. and the one-second vital capacity 2,400 cc. Only a few minute petechiae of the rectal mucosa were seen on proctoscopic examination. Results of chest roentgenograms had not changed significantly. At the time of his latest follow-up, in April, 1958, he was employed and asymptomatic.

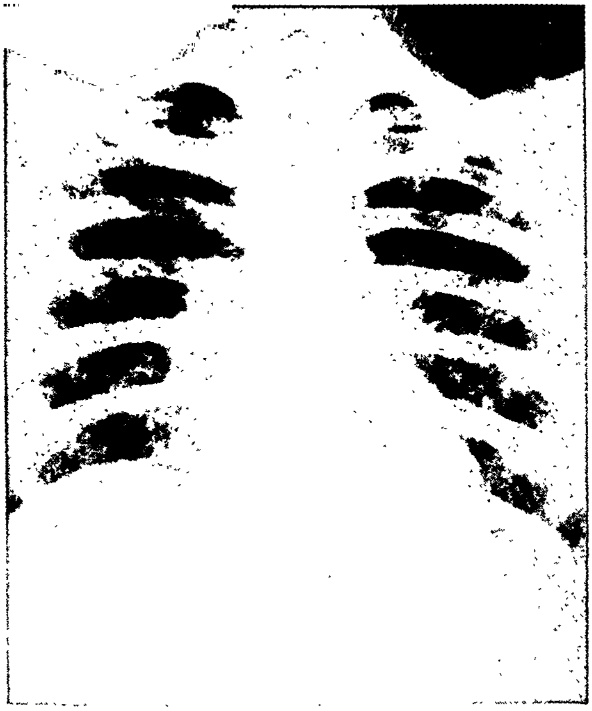

Fig. 1 (case 1).—Chest roentgenogram showing diffuse infiltrates of lungs.

Case 2.—This 20-year-old Puerto Rican male soldier was admitted to the tuberculosis section on April 30, 1957, because of a diffuse lung disease. Experience with the previous case led to a clinical diagnosis of pulmonary schistosomiasis which was confirmed by lung biopsy.

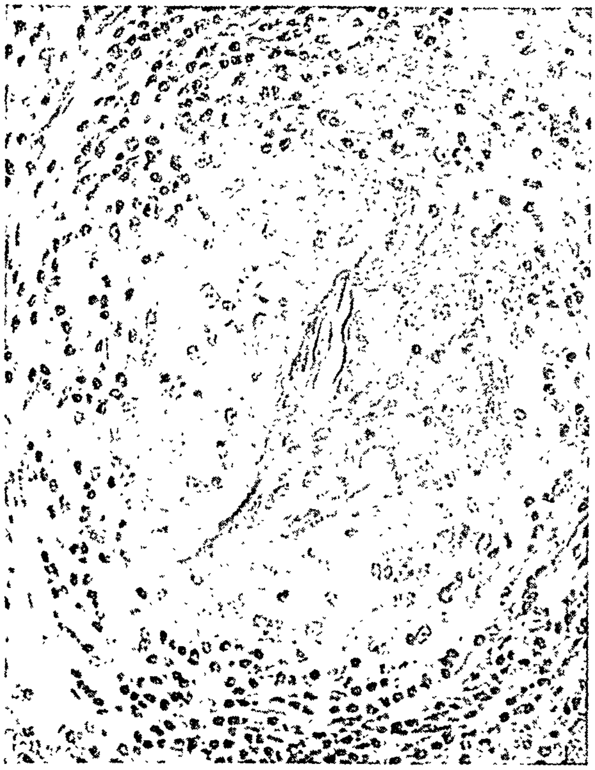

Fig. 2 (case 1).—Photomicrograph of lung biopsy specimen. Clear area within giant cell represents fragment of ovum.

The patient was born and lived in the vicinity of Comerio, Puerto Rico, until entering the U. S. Army in September, 1955. It could not be determined specifically when he contracted schistosomiasis. He was transferred to the United States in November, 1955, and was subsequently stationed at Fort Chaffee, Arkansas, and Fort Sill, Oklahoma.

He spent a 30-day leave at his home in Puerto Rico during December, 1956, and January, 1957. Three weeks after his return he developed a headache, mild fever, malaise, nonproductive cough, sore throat, and diffuse anterior chest pain aggravated by coughing. He was hospitalized at Fort Sill on Feb. 18, 1957, where at physical examination he appeared mildly ill. Temperature was 99.4 F; pulse, 80 per minute; blood pressure, 118/84 mm. Hg; respirations, 16 per minute. The pharynx was moderately inflamed and there was lymphoid hyperplasia. Auscultation over the lungs revealed diffuse inspiratory and expiratory wheezes. Scattered moist rales were localized in both lower lungs. The examination was otherwise normal. The white blood cell count was 9,000 per cubic millimeter with 59% neutrophils, 35% lymphocytes, 2% monocytes, and 4% eosinophils. Hemoglobin level was 15.3 Gm. per 100 cc., and erythrocyte sedimentation rate 16 mm. per hour. Chest roentgenograms showed diffuse infiltrative densities in both lungs. He was treated with antibiotics for one week after which the symptoms and physical findings cleared but the roentgenographic abnormalities persisted.

On his arrival at Fitzsimons Army Hospital he was asymptomatic and the results of the physical examination were essentially normal. The lungs were clear on auscultation and neither the liver nor the spleen was palpable. A repeat white blood cell count showed 11,000 per cubic millimeter, with 54% neutrophils, 38% lymphocytes, 3% monocytes, and 5% eosinophils. Hemoglobin level was 14.8 Gm. per 100 cc., and erythrocyte sedimentation rate 23 mm. per hour. Result of a serologic test for syphilis was negative. Urinalysis was normal. Results of liver function studies were normal except for a thymol turbidity of 7 units. Total serum protein level was 8.4 Gm. per 100 cc., with albumin, 3.2 Gm. and globulin 5.2 Gm. The electrophoretic pattern of the serum proteins was albumin, 42.5%; alpha-1 globulin, 4.9%; alpha-2 globulin, 14.7%; beta globulin, 16.9%; and gamma globulin, 21.0%. Results of the histoplasmin test and the second-strength PPD skin test were positive; result of the coccidioidin test was negative. Results of the histoplasmin complement-fixation test were positive in titers of 1:8 and 1:16 on separate tests. Results of the serologic tests for blastomycosis and coccidioidomycosis were negative. Repeated gastric washings disclosed no M. tuberculosis or fungi. Ova of S. mansoni were found in the stools but none could be recovered in the sputum even after the administration of expectorants. A scalene node biopsy gave normal results. Serial sections of a needle biopsy of the liver showed occasional poorly circumscribed pseudotubercles in the portal areas. Several of these pseudotubercles contained fragments of egg shell within foreign body giant cells. A wedge biopsy of the right lung, obtained July 22, showed frequent small and medium-sized histiocytic granulomatous areas containing numerous eosinophils. The small bronchi and blood vessels wit these areas were necrotic. Early fibrosis was present. Fr quent pseudotubercles containing ova were seen; one ov had a prominent lateral spine, positively identifying it S. mansoni (fig. 3). No angiomatoids were found.

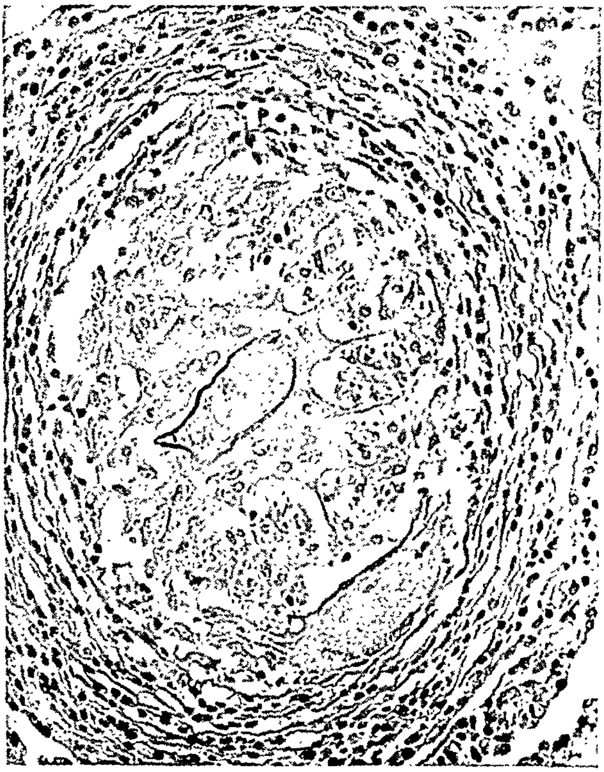

Fig. 3 (case 2).—Photomicrograph of lung biopsy specimen showing ovum of S. mansoni within giant cell.

Chest roentgenograms had a diffuse mottled appearan with nodular densities measuring 2 to 3 mm. in diamet and a reticular pattern of increased lung markings (fig. 4 The over-all appearance was similar to that seen in silicos Between February and July the lesions seemed to becom more prominent. Miniature chest roentgenograms of 195 1954, and January, 1955, showed no definite lesions; how ever, in May, 1956, a portion of the right upper lobe w visible on films of the shoulder and these showed nodul infiltrates of the lung. Pulmonary function studies show vital capacity, 3,700 cc. or 85% of the predicted norm one-second vital capacity, 91.5% of the observed; and ma mum breathing capacity, 106.5 liters per minute or 80% the predicted normal. Electrocardiograms did not show e dence of pulmonary hypertension.

During his early course at this hospital he had seve episodes of respiratory distress during the night and auscult tion over the lungs revealed diffuse expiratory wheez These were promptly relieved by rectal administration aminophylline. After the diagnosis of pulmonary schisto miasis was established he received two courses of stiboph The first was begun on Aug. 6; and after 45 cc. was a ministered in doses of 5 cc. intramuscularly on altern days, he developed T-wave inversions on the electrocard gram and complained of general malaise. After a one-mon rest period he was given a second course of treatment c sisting of 50 cc. of stibophen which he tolerated with difficulty. Follow-up sputum and stool specimens were p sistently negative for ova of S. mansoni. The chest roentge grams had not shown improvement when he was returned duty on Oct. 24. On follow-up in April, 1958, he complai of shortness of breath, tiredness, and chest pain, but additional information is available.

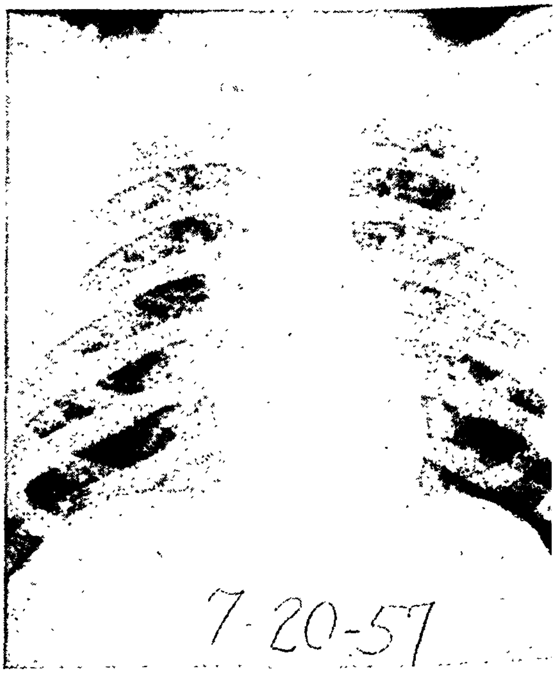

Fig. 4 (case 2).—Chest roentgenogram showing diff mottling.

Pathogenesis

There are three species of schistosomes (blood flukes) which commonly infect man. They are S. haematobium, which is found in the Middle East and Africa; S. mansoni, which was originally indigenous to Africa but was spread to the West Indies and South America during the slave trade; and S. japonicum, which is found only in the Far East. The schistosomes have similar life cycles but they differ in the organs to which they migrate and in the size and shape of the ova. Schistosomiasis, also known as bilharziasis, is so common in many areas of the world that it is estimated that approximately 5% of the world's population is infected.

The life cycle of the schistosomes involves man and various animals as reservoirs and specific species of snails as intermediate hosts. The ova pass from man in the urine or feces and hatch in water, liberating a free-swimming miracidium. The miracidia must penetrate the proper species of snail where two generations of sporocysts develop before the fork-tailed cercariae emerge. The cercariae swim about vigorously and easily penetrate the skin of persons washing, bathing, or wading in infected water. Infection can also take place by ingestion of cercariae. Penetration is aided by the lytic action of enzymes. The tail detaches and the larva is carried through the veins into the right heart, through the lungs, and into the systemic circulation. The passage through the pulmonary capillaries requires approximately three days and may be associated with transient signs and symptoms consisting of cough, rales, bronchopneumonia, sputum, fever, urticaria, and leukocytosis with eosinophilia.[2] Only those larvae survive that find their way to the intrahepatic portions of the portal vein, where they mature into male and female adult worms and then migrate against the blood stream to the organs of predilection; S. japonicum prefers the small intestine, S. haematobium the bladder, and S. mansoni the large intestine. The female of the pair deposits her eggs in the venules and, if she is not destroyed by the body defenses or by treatment, may continue to deposit eggs for as long as 20 years. In experimental infections in the hamster, the average number of eggs laid daily by a single worm was found to be 300 for S. mansoni and 3,500 for S. japonicum.[3] The ova become dislodged and may be disseminated to distant organs. Many are discharged into the portal circulation and become implanted in the liver where they often cause cirrhosis.

It has been postulated that the ova reach the lungs by way of the coronary vein and esophageal anastomoses or through the inferior hemorrhoidal plexus and the inferior vena cava. Experimental studies have shown that ova might reach the lungs by way of the vascular shunts in the liver.[4] A lymphatic route via the thoracic duct is a theoretical possibility since there are cases reported in which mesenteric lymph nodes contained many ova.[5] Once in the lungs the ova penetrate the arterioles and are quickly surrounded by inflammatory cells which eventually form pseudotubercles. These may be located in the adjacent interstitial tissue, respiratory bronchioles, or alveolar walls. In most cases the microscopic pseudotubercle will be the only pathological finding. In approximately 1 or 2% of all cases with pulmonary involvement there is extensive subacute and chronic granulomatous reaction sufficient to be detectable on chest roentgenograms. In addition to pseudotubercles there may be focal collections of histiocytes, eosinophils, chronic inflammatory cells, and fibroblasts. The arterioles may show acute and chronic angiitis. Angiomatoid formation is postulated to result from passage of ova through the arterial walls with focal destruction of the media. Shaw and Ghareeb [6] considered these to be pathognomonic of pulmonary schistosomiasis. Lopes de Faria [7] has pointed out how arteriovenous aneurysms may form and cause shunting of blood with clinical cyanosis.

Comment

Although scattered lung lesions are common in schistosomiasis, diffuse lesions such as have been described are not. In 1938, Shaw and Ghareeb,[6] from the Egyptian University, Cairo, published a detailed review of 282 autopsies on patients with schistosomiasis. They found that 95 (33%) had lung lesions which were divided as follows: 1. Parenchymatous tubercles only were found in 83 cases. 2. Focal arterial lesions appeared in 6. 3. Widespread arterial lesions producing the manifestations of Ayerza's disease were found in 6. In a study of 248 autopsies on patients with schistosomiasis, Martinez-Rivera and Koppisch [8] in Puerto Rico found that 161 (65%) had lung lesions, but in only three cases were the pulmonary lesions considered of clinical importance.

Chest roentgenograms may not always yield abnormal results, even though there are extensive lung lesions causing physiological abnormalities. This presents a difficult diagnostic problem, especially outside the endemic areas. The physiological abnormalities that occur in pulmonary schistosomiasis are (1) increased pulmonary vascular resistance and pulmonary hypertension, produced by diffuse obliterative endarteritis; (2) shunting of pulmonary artery blood as a result of extensive formation of arteriovenous anastomoses; and (3) restriction of ventilation produced by the fibrotic reaction in the lung. Both of the patients whose cases we have reported had restricted ventilation but little can be said about circulatory disturbances in their lungs since the critical physiological studies were not performed. The goal in their treatment was not to reverse the pathological changes but to prevent further extension of the disease.

Summary

Schistosomiasis may result in many serious complications and it is therefore desirable to survey individuals who come from endemic areas and to treat those who are infected. In patients coming from endemic areas, pulmonary schistosomiasis *should be included in the differential diagnosis of* scattered or diffuse infiltrative lesions of the lungs.

FEVER OF OBSCURE ORIGIN—THE VALUE OF ABDOMINAL EXPLORATION IN DIAGNOSIS

REPORT OF SEVENTY CASES

Joseph E. Geraci, M.D., Lyle A. Weed, M.D.
and
Donald R. Nichols, M.D., Rochester, Minn.

A study of the diagnostic value of laparotomy was made in 70 patients with febrile states that had lasted longer than two weeks and had been explained by repeated thorough physical and laboratory examinations. In 21 patients exploration of the abdominal cavity revealed malignant disease, and in 10 of these the lesion was a lymphoblastoma. In 15 patients evidence of specific infections was found, and in 5 of these it was tuberculous peritonitis. The surgical intervention entailed little risk. Its diagnostic value in cases of fever of obscure origin was evident.

Fever of obscure origin represents one of the most fascinating problems in differential diagnosis in the field of internal medicine. By fever of obscure origin we mean continuous fever of more than two weeks' duration or intermittent fever for a longer period for which a cause has not been found after careful, repeated interrogation, thorough, general physical examinations, and extensive laboratory studies. Such fever tests medical knowledge and diagnostic acumen to the utmost. The problem it presents has always been with us but seems to have assumed increased importance because of the availability of newer therapeutic agents, such as the antibiotics, cortisone, nitrogen mustard, and others.

From the sections of medicine (Drs. Geraci and Nichols) and bacteriology (Dr. Weed), Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Many of the problems of obscure fever are the result of atypical clinical syndromes and variations of commonly known diseases; only rarely is a patient with such fever found to have an unusual disease.

We do not propose to discuss normal body temperature and the normal physiology involved in the regulation of body temperature. This can be found in any good physiology textbook and is summarized beautifully in the Croonian lecture of 1957 by Sir George Pickering.[1] Suffice it to say here that normal body temperature varies widely from person to person, and values up to 100 F (37.8 C) by mouth may be considered within normal limits in most people. When the temperature begins to be consistently more than 100 F by mouth, then one begins to think in terms of a febrile state and the possible cause for it. In some patients with anxiety-tension states the temperature may occasionally be slightly more than 100 F—as high as 101 F (38.3 C) and occasionally even higher—in the absence of any recognizable organic disease.[2]

Many good reviews of fever of obscure origin have appeared recently, including the volume by Keefer and Leard.[3] Other important reviews are those of Hamman and Wainwright,[4] Beeson,[5] Bennett,[6] Albrecht,[7] and Böttiger.[8]

Most observers have classified obscure fevers according to broad groups, as Beeson[5] has done: (1) infections of either localized or systemic variety, (2) malignant diseases, (3) collagen diseases, and (4) a miscellaneous group. An alternative and perhaps a more helpful way is to classify obscure fevers by body systems. Such a classification has the advantage of being an aid in differential diagnosis as one carefully questions the patient for possible clues which might lead to a diagnosis. Several such classifications have appeared.[9] In questioning the patient, we like to start at the top, with the central nervous system, and work down.

Our interest in obscure fever was aroused several years ago when we began to observe a number of patients with such fever in whom a definitive diagnosis could not be established when they were dismissed from the clinic. Among our colleagues and ourselves there was no unanimity of opinion regarding the value of exploratory laparotomy in patients with fever of unknown origin. Many were actually opposed to laparotomy in these patients when there were no signs or symptoms referable to the abdomen. We then decided to advise exploratory laparotomy in patients with obscure fever after a thorough clinical investigation revealed no diagnosis and yet indicated that the patient might have organic disease as the basis for the fever. Here we shall report our observations in 70 such cases.

Materials and Methods

All 70 patients were given thorough, detailed, repeated interviews for purposes of obtaining clues to the diagnosis, thorough repeated general physical examinations, numerous laboratory tests and x-ray examinations, biopsies as indicated, and, in selected instances, therapeutic trials with antibiotic or chemotherapeutic agents. Peritoneoscopy was not performed. These patients had febrile states of longer than three weeks' duration, and the cause of the fever could not be determined by any of the foregoing procedures. They represented patients seen personally and recently by us, patients seen and recalled by our colleagues, and other cases recorded in the files of the Mayo Clinic. Forty-one were males, and 29 were females. They ranged in age from 1 to 71 years, the average being 48 (51 years if the five patients in the pediatric age group, under 16, are excluded).

Microbiological procedures used included routine cultures for the common aerobes and anaerobes with use of fresh-meat-infusion blood agar, brain broth, and thioglycollate broth; cultures for Brucella; cultures for acid-fast bacilli with incubation at 37 and 32 C; cultures for fungi with use of mediums and techniques known to be useful for all the deep mycotic organisms; cultures for Leptospira; and inoculation of mice to detect Toxoplasma. When indicated, cultures were also made for Leishmania and Trypanosoma. In all cases material was examined directly with the aid of acid-fast stain, Wright's stain, and dark-field illumination. In most cases multiple specimens of tissue were examined in addition to the usual materials of blood, spinal fluid, sputum, urine, and stools. In a few cases special studies for viruses and rickettsias were made by complement-fixation test, inoculation of animals, or tissue culture.

In 30 of the 70 patients, there were no subjective symptoms or objective findings referable to the abdomen. Of the other 40 patients, 15 had subjective complaints and 34 had objective findings, 9 of the 40 having both. The subjective complaints referable to the abdomen consisted of tenderness, either localized or diffuse, and vague soreness, vague distress, actual aching, or other types of pain. Among the objective findings was enlargement of the liver, present in nine cases, in two of which the liver was also tender; it was palpable or questionably palpable in an additional 12 patients, in 2 of whom it seemed to be tender also. The spleen was palpable and enlarged in 19 patients; in one of these patients the enlargement was observed only on x-ray examination of the stomach. Ascites was present in one. There was a suggestion of an adnexal mass in one patient and an actual adnexal mass in another. There was splinting of the muscle of the left flank in one patient. These complaints and findings were not of diagnostic value.

The results are given in the table and are presented here by group: malignant disease, 21 patients; specific infections, 15; indeterminate disease, 14; entirely negative findings, 14; and miscellaneous diagnoses, 6. Of the 14 patients with entirely negative results on exploration, 8 had no signs or symptoms referable to the abdomen and 6 had signs or symptoms or both.

Results of Exploratory Laparotomy in Seventy Patients with Fever of Obscure Origin

Group	Condition	No. of Cases
1	Malignant disease (21 patients)	
	Lymphoblastoma	10
	Cancer, pancreas	5
	Cancer, kidney	2
	Cancer, sigmoid colon	1
	Cancer, gallbladder	1
	Hepatoma	1
	Retroperitoneal malignant lesion (from heterotopic adrenal tissue?)	1
2	Specific infections (15 patients)	
	Tuberculous peritonitis	5
	Histoplasmosis*	2
	Brucellosis of spleen (Brucella suis, 1) and of spleen and liver (1†)	2
	Abscess of liver (Staphylococcus pyogenes var. aureus)	2
	Viral hepatitis	1
	Granulomatous hepatitis (gram-negative bacillus)	1
	Streptococcus mitis bacteremia without clinical endocarditis	1
	Pyogenic abscess of spleen (Str. mitis)	1
3	Indeterminate disease (14 patients)	
	Granulomatous disease of undetermined cause (8 patients)	
	Granulomatous lymphadenitis	3‡
	Granulomatous abscesses of liver and hepatitis	3
	Granulomas of liver and regional lymph nodes	1
	Granulomatous disease of liver and bone marrow	1
	Nonspecific inflammation of lymph nodes and liver	5§
	Pyelonephritis?	1
4	Entirely negative results (14 patients)	
	Now well, no diagnosis at any time	8
	Died without diagnosis, no autopsy	2
	Rheumatoid arthritis	2
	Henoch's purpura	1
	Collagen disease?	1
5	Miscellaneous diagnoses (6 patients)	
	Thrombosis and thrombophlebitis of mesenteric veins and venules	1
	Periarteritis nodosa	1
	Endometriosis	1
	Common-duct stone (1); chronic cholecystitis and lithiasis (1)	2
	Intestinal lipodystrophy	1
	Total	70

* One case previously reported by Broders and co-workers.[11]

† Previously reported by Osmundson and co-workers.[12]

‡ In one patient biopsy of lymph node in home community at time of initial abdominal exploration and cholecystectomy revealed noncaseating granulomas. Exploration at Mayo Clinic showed only nonspecific inflammation in some enlarged para-aortic nodes.

§ One patient had leukocyte counts of 13,000-17,000 per cubic millimeter and microabscess in bone marrow, as well as enlarged para-aortic nodes and enlarged spleen.

Malignant Disease

In the 10 patients with lymphoblastoma no adenopathy was observed. The spleen was palpable in seven patients, and the liver apparently was enlarged and tender clinically in only one case. There was nothing from the clinical examination that could have led to a diagnosis. In two patients the fever was cyclic, in one for 1½ years and in the other for 11 years. In the latter patient a diagnosis of cyclic or "periodic" fever had been made until laparotomy, 11 years after the onset, revealed Hodgkin's disease. In seven patients the fever was continuous, occurring daily but of an irregular, remittent character.

The two patients with carcinoma of the kidney presented unusual diagnostic problems. One had two explorations before the diagnosis was made. Review of the excretory urograms indicated in retrospect that a diagnosis of malignant disease perhaps could have been entertained before the first surgical exploration. Despite this, the results of thorough exploration at the time of the first operation were negative. The other patient, who had had low-grade fever for six months, had normal-appearing excretory urograms and right retrograde urograms. He declined to have exploratory laparotomy. Three months later, laminographic examination of the left renal region elsewhere revealed a possible renal lesion; exploration disclosed renal carcinoma.

Four patients with cancer of the head of the pancreas had extensive metastasis to the liver. Two of these patients had mild soreness and pain in the right upper quadrant. The liver was not enlarged in any of them but was just palpable in one. In one patient exploration revealed a large amount of bile in the peritoneal cavity, and bile peritonitis. The superior border of the liver contained many nodules. One nodule in the dome of the liver was adherent to the diaphragm and apparently had ruptured, with the liberation of bile. Biopsy of this lesion revealed grade-3 squamous cell carcinoma which, the surgeon thought, probably arose from the gallbladder. However, subsequent postmortem examination revealed that the primary lesion was in the pancreas.

The patient with malignant disease of the sigmoid colon underwent abdominal exploration because of the finding of asymptomatic cholelithiasis. She had had no symptoms or signs that were referable to the abdomen or the gastrointestinal tract. She had had fever cyclically for about seven years, but six months before she came to the clinic the fever had become almost continuous. Exploration of the abdomen at the time of cholecystectomy revealed an inflammatory mass in the sigmoid. A second surgical exploration subsequent to suitable preparation of the intestine revealed a polypoid, grade-1 adenocarcinoma extending through the muscle and serosa to involve the pericolonic fat; the sigmoid was resected. No lymph nodes were involved. Proctoscopic examination and x-ray examination of the colon had not been done. The patient was completely well after three years and had had no fever. Two other patients with a malignant lesion of the sigmoid associated with prolonged fever have been seen, one with extensive metastasis to the liver which was not evident before exploration and the other without metastasis. Proctoscopic examinations in both patients revealed annular and ulcerative lesions in the absence of any other findings. These two patients are mentioned because it could not be determined without laparotomy whether other causes for the obscure fever were present, but they are excluded from the series because of diagnosis by proctoscopy. Malignant disease of the sigmoid alone has been associated with fever of unknown origin, and similar cases have been described in the literature.[10]

In the patient with hepatoma the liver was irregular, nodular, firm, and tender and was felt about 8 fingerbreadths below the right costal margin. The patient's temperature ranged up to 103 F (39.4 C), and he had chills and vague, recurring pain in the upper part of the abdomen. The diagnosis was made at surgical exploration and confirmed at postmortem examination.

The patient with retroperitoneal malignant neoplasm had had an irregular daily temperature ranging up to 101 F (38.3 C), together with malaise, weariness, fatigue, and night sweats for four months. The examination revealed only some enlarged axillary lymph nodes on the left. Biopsy of these revealed only "hyperplastic" nodes; the cultures gave negative findings. The only positive laboratory findings were increased sedimentation rate (109 mm. per hour by the Westergren method), marked rouleau formation on the blood smear, and a positive skin reaction to the tuberculin (purified protein derivative) test. All other tests and examinations gave negative results. Exploratory laparotomy disclosed only a cluster of enlarged firm lymph nodes at the ligament of Treitz, situated on the aorta and vena cava. No primary source of the neoplasm could be found. Biopsy revealed a grade-4, clear-cell, malignant lesion which, it was thought, might have arisen from heterotopic adrenal tissue.

Specific Infections

In patients with tuberculous peritonitis the abdomen can appear to be almost normal on physical examination despite the extent of the disease that is found in it. In three of five cases physical examination of the abdomen gave negative results; there was no evidence of fluid. In the fourth case moderate ascites was present. This patient had had splenectomy in his home community for what was thought to be thrombocytopenic purpura. Granulomatous lesions had been seen at the time of exploration, and it had been thought that a fungous disease was the cause of the difficulty. Reexploration of the abdomen with biopsy at the clinic after it had not been possible to make a diagnosis revealed tuberculosis when acid-fast bacilli were found in smear and culture. In the fifth case abdominal examination revealed some tenderness in the right lower quadrant and the sensation of a mass in the left side of the pelvis. In the four patients on whom tuberculin skin tests were performed the reaction was positive. In all five cases the diagnosis was proved bacteriologically.

In two patients a definite diagnosis of histoplasmosis was made at the time of exploration. In one, exploration was performed for diagnosis because it was thought that hepatic disease was the basis for the fever. Biopsy of the liver at the time of laparotomy revealed Histoplasma capsulatum. Postmortem examination elsewhere revealed histoplasmosis of the heart valves also. Clinically, the patient had presented some features of bacterial endocarditis, but the results of blood culture were negative. This case has been reported previously.[11] The second patient had recurring chills and fever, malaise, weakness, loss of weight, sweats, and an enlargement of the spleen together with pancytopenia over a period of six months. Abdominal exploration and splenectomy were performed in an attempt to make a diagnosis. H. capsulatum was cultured from the noncaseous granulomatous lesions of the spleen and liver.

One of the two patients with brucellosis had had periodic fever of 17 years' duration resulting from Brucella suis infection of the spleen. This case will be reported separately. Cure followed splenectomy and combined antibiotic therapy with tetracycline and streptomycin. The other patient with brucellosis had had fever each summer for 14 years; this case has been reported previously.[12] Brucellosis was suspected when needle biopsy of the liver revealed granulomas; cultures of the granulomas were negative for B. suis. The Brucella agglutination titer was then found to be 1:800. A combination of tetracycline and streptomycin had been given for two weeks when exploratory laparotomy became necessary because of moderately severe pain in the left upper part of the abdomen. Only then was a diagnosis of brucellosis established by culture.

In one of the two patients with hepatic abscess the liver was (questionably) slightly enlarged, and tender. The patient who had hepatitis without jaundice was a surgeon who was most anxious to know the cause of his fever.

The patient with granulomatous hepatitis was a 1-year-old who had been ill for about six months with irregularly occurring fever, chills, anemia, thrombocytopenia, hepatomegaly, and splenomegaly. Much antibiotic therapy given at home had apparently not been helpful. The temperature after admission to the clinic had been irregular, going as high as 105.4 F (40.9 C), and fever had been present continuously for two weeks. Cultures of the blood, urine, and stools gave negative results. It was thought that exploration would be the best method to settle the diagnostic doubt. At exploration the spleen was found to be four times normal size; the liver was enlarged, and histopathologically it was the site of "granulomatous hepatitis." There were no enlarged retroperitoneal nodes. No discrete abscesses or granulomas were seen. Cultures for B. suis, acid-fast bacilli, and fungi gave negative results. However, an unidentified gram-negative bacillus, not a recognizable pathogen, was isolated. The patient died suddenly two days after operation. One can only speculate on whether the gram-negative bacillus was causative or a contaminant.

The patient who had Streptococcus mitis bacteremia without clinical evidence of endocarditis underwent abdominal exploration because no diagnosis could be made clinically even though one of the many blood cultures showed Str. mitis. He was having recurrent daily chills and fever. He had had cholecystic disease and had undergone cholecystectomy previously and also surgical treatment for chronic relapsing pancreatitis. Clinically the liver was slightly enlarged and tender, and it was thought that the disease process causing the febrile state was probably located in the abdomen. At operation, exploration was difficult; nothing was found except many adhesions in the cholecystic bed and at sites of previous surgical treatment. Cultures obtained from these areas at exploration revealed Str. mitis. Appropriate therapy with penicillin and streptomycin for a two-week period was curative.

The patient with a Str. mitis splenic abscess which ruptured retroperitoneally had had five episodes of fever (temperature up to 103.4 F [39.5 C]) and chills lasting two to five days over a period of two or more months. It was thought that a good response to antibiotics had occurred with each attack. The patient had had intermittent pain in the left upper abdominal quadrant for more than eight years; during the same two months of the febrile episodes, the distress had been more pronounced and he had some characteristics of pleuritic pain. There had also been anorexia and a loss of about 20 lb. (9.1 kg.). Study of the patient in his home community had revealed no abnormalities. Examination at the clinic disclosed only a slightly palpable liver and some tenderness in the left upper quadrant of the abdomen. Positive laboratory findings were as follows: sedimentation rate, 120 mm. in one hour; hemoglobin level, 11.7 Gm. per 100 cc. of blood; and moderate rouleau formation on the blood smear. The left hemidiaphragm was slightly elevated. X-ray examination of the entire gastrointestinal tract and kidneys gave negative results. All other tests also were not helpful. Exploratory laparotomy revealed a mass of induration across the upper part of the abdomen in the retroperitoneal region. An abscess of the spleen had perforated retroperitoneally, and the infection had extended up under the tail of the pancreas, across the midline; splenectomy was performed. The other structures were normal. Cultures revealed only green-producing streptococci sensitive to less than 0.05 unit of penicillin per cubic centimeter. Postoperative antibiotic therapy with penicillin brought rapid improvement and cure.

Indeterminate Disease

The patients in group 3 had nonspecific findings on exploration. In the eight patients with unidentified granulomatous disease (granulomatous lymphadenitis, hepatitis, hepatic abscesses, or disease of the bone marrow), the liver was enlarged slightly in three and the spleen was palpable and enlarged in two at the time of physical examination. All cultures from multiple biopsy specimens of involved tissues removed at operation were negative for acid-fast bacilli, Brucella, fungi, and other bacterial pathogens. Noncaseating granulomatous lesions were noted in six of these eight patients and caseation in two. One of the last two patients had had two laparotomies, one in Hawaii and one at our clinic. The findings in the liver were the same, and the cultures were negative for any pathogens on both occasions; the liver was studded with many abscesses containing granular, thick, greenish-yellow material. In six of the eight patients the febrile episodes disappeared and the patients have remained well; the other two died. One of the deaths was that of a 3-year-old boy in whom a diagnosis of granulomatous hepatitis and abscess was made at laparotomy. Febrile episodes continued until death occurred 16 months after operation. The patient had many of the features of the entity described by Berendes and co-workers[13] as "fatal granulomatosis of children." The other death, that of a 50-year-old man, was attributed to an increasingly severe pancytopenia and a hypocellular condition of the bone marrow resulting from a marked granulomatous reaction of the marrow. The cause of the latter was obscure.

In six patients with nonspecific inflammatory disease, a definitive diagnosis could not be made from abdominal exploration. One patient had a mesenteric lymph node removed at home. The histological section reviewed by a clinic pathologist was reported as showing noncaseating granuloma "consistent with sarcoid." The nodes had been removed at the time of cholecystectomy. Laparotomy at our clinic revealed a spleen that was three times normal size, a para-aortic node 1 cm. in diameter, and some mesenteric nodes that were thought not to be abnormal. Biopsies of the liver and the rectus muscle gave negative results. The para-aortic node showed "inflammation" and the mesenteric nodes showed "reticulum hyperplasia." All cultures gave negative results. Follow-up examination three months later showed the patient to be improving, gaining weight, and afebrile.

In a second patient abdominal exploration gave negative results except for many creamy-white, raised, glistening, punctate nodules 2 mm. in diameter on the liver and spleen. The pathologists reported "normal liver except for focal subcapsular accumulations of lymphocytes." All cultures gave negative results. Biopsies of axillary lymph nodes, rectus muscle, and the appendix also gave negative results. The fever subsided postoperatively.

A third patient had only some slightly enlarged nodes in the mesentery of the small intestine and in the periaortic region; also, a node that measured 2 by 1.5 by 0.7 cm. was present retroperitoneally above the head of the pancreas. The spleen was two and one-half times normal size. All cultures of the nodes and other tissues gave negative results. Histopathological examination of the nodes revealed "inflammatory reaction with hemosiderosis" of doubtful cause. Sections of a node that had been removed in the patient's home community showed "rather marked reticuloendothelial hyperplasia." The patient was well five years later.

A fourth patient had only slight enlargement and mottling of the liver with focal collections of polymorphonuclear leukocytes and lymphocytes in the liver. These were thought to be nonspecific findings. No other intra-abdominal abnormality was noted. Postoperatively 20 mg. of prednisone (Meticorten) given daily for three weeks curbed the increase in temperature somewhat. However, low-grade fever, weakness, anorexia, and deterioration persisted. All cultures for pathogens had given negative results. After dismissal of the patient, his condition deteriorated further and he died at home about four months later. Unfortunately, autopsy was not performed, and the cause of the fever remained indeterminate.

A fifth patient had what appeared to be an ulcerating lesion of the lower pole of the left kidney, as revealed by excretory and retrograde urograms; a lower calyceal deformity was also evident. Abdominal exploration gave negative results; the left kidney was felt to be normal. The lower one-third of this kidney was resected. Histopathological examination revealed only mild inflammatory clusters of lymphocytes and foci of calcification. The urologist thought that these minimal pyelonephritic changes were not sufficient to account for the fever (102 to 104 F [38.9 to 40 C]), sweats, and occasional chills that had been experienced for two months preoperatively. The patient's condition improved, and the episodes of fever diminished postoperatively and eventually disappeared. Cultures of the urine had revealed Aerobacter aerogenes; cultures of the excised renal tissue gave negative results for bacterial pathogens.

The sixth patient had two laparotomies at the clinic. The first was in 1948, at which time cholecystectomy was done; the liver was large and boggy, and a moderate hepatitis was evident. The gallbladder contained a large solitary stone. The pancreas was firm and slightly enlarged. The spleen was two times normal size. Histologically, nests of inflammatory cells were observed along the liver cords. Cultures gave negative results. The second exploratory laparotomy, performed in 1952, revealed only mild fibrous pericholangitis. The condition of the liver was improved, and the spleen was smaller. The patient continued to have recurring bouts of fever with severe anorexia every three or four months which lasted 7 to 10 days; he continued to lose weight and had recurring bouts of abdominal pain. His condition had deteriorated when he was last seen at the clinic in 1955. He looked emaciated and was thought to have some pathological change in the right side of the abdomen. He refused further tests and further exploration. Three months later the home physician found a large mass in the right lower quadrant which seemed to fill the entire pelvis. Incision and drainage revealed much pus; culture at home gave negative results. The patient permitted no other studies by the home physician. His condition continued to deteriorate. The diagnosis has remained indeterminate.

Entirely Negative Results

In group 4 (14 patients), abdominal exploration did not reveal any disease or abnormality. Eight of the patients are now well, and in them no diagnosis has ever been made. One of these patients, however, was suspected of having histoplasmosis; a single episode of persistent low-grade fever had been present for six weeks. Abdominal exploration gave completely negative results. The skin reaction had been positive for histoplasmosis. Two months after surgical exploration the patient was well and afebrile; miliary nodules were seen at the bases of both lungs. A presumptive diagnosis of histoplasmosis was made. However, the diagnosis was not proved.

Two patients died at home, possibly from malignant disease; however, postmortem examinations were not made. In two patients—a 4-year-old boy and a 20-year-old woman—signs and symptoms of rheumatoid arthritis finally developed. In one patient, Henoch's purpura was finally diagnosed. One patient became afebrile with postoperative cortisone therapy; review of the entire clinical problem suggested a diagnosis of collagen disease.

Miscellaneous Diagnoses

The patient with thrombophlebitis of the mesenteric veins and venules had had intermittent fever for about six weeks. She was dismissed from the hospital after thorough study and when the temperature had become normal. That same evening abdominal pain developed; she was readmitted to the hospital and subjected to exploratory laparotomy.

The patient with the diagnosis of periarteritis nodosa was studied thoroughly at the clinic and underwent abdominal exploration in the home community. Extensive examinations at our clinic had revealed only chronic cholecystitis with cholelithiasis.

The patient with endometriosis had had brucellosis six years before the onset of her fever. She had a small adnexal mass. The Brucella agglutination titer was 1:200. It was felt that a Brucella abscess might be present. Exploration revealed only endometriosis. The patient had not had any previous estrogen therapy or surgical treatment.

The patient with choledocholithiasis had been referred to the clinic with the diagnosis of probable bacterial endocarditis. Fever had been present for seven weeks at home, and it continued here. Extensive study resulted in suggestions of many other diagnoses. Details of the history were difficult to obtain. The patient had recurrent febrile episodes with chills, night sweats, undocumented jaundice (one episode), anorexia, and vague pain in the right upper part of the abdomen; these episodes on occasion were suggestive of biliary colic. Examination revealed severe tachycardia, an enlarged rheumatic heart with mitral stenosis and atrial fibrillation, and, eventually, a palpable, distended gallbladder. The positive laboratory results were increased sedimentation rate (110 mm. in one hour), anemia with eosinophilia and marked rouleau formation evident on the blood smear, and grade-3 retention of dye with the sulfobromophthalein test of hepatic function. Many blood cultures gave negative results. Needle biopsy of the liver revealed cirrhosis. Laparotomy disclosed distention of the gallbladder and enlargement of the liver and spleen. The common duct was greatly dilated—so much so that the surgeon thought that a choledochal cyst was present. A single stone, 1.3 cm. in diameter, was found. Choledochoduodenostomy, removal of the stone, and biopsy of the liver were performed. The remainder of the abdominal exploration gave negative results. Histopathological examination of sections from the liver revealed periportal infiltration with neutrophils and lymphocytes. Postoperatively the patient became afebrile.

The patient with cholecystitis and cholelithiasis had had intermittent febrile episodes with chills, malaise, arthralgias, and sweat lasting about 24 hours, the fever itself being present during only four to six hours of the entire episode. There were no symptoms referable to the gastrointestinal system and no history of jaundice. The only abnormal laboratory findings consisted of slightly increased serum bilirubin level (0.5 mg. per 100 cc. direct and 0.7 mg. indirect) and a sulfobromophthalein retention of 8%. The cholecystogram was interpreted as showing a normally functioning gallbladder. At exploration, subacute gangrenous cholecystitis with cholelithiasis was found. The gallbladder was tense, edematous, and gangrenous. It was amazing that the patient had no symptoms referable to the right upper part of the abdomen.

The patient with intestinal lipodystrophy (Whipple's disease) was a 44-year-old man with a history of periodic fever for three and one-half years; initially, for a 16-month period, the three-to-four-day periods of fever, chills, sweats, malaise, and arthralgias occurred at monthly intervals. The patient said they took place "almost like clockwork." Then the febrile episodes recurred with gradually decreasing time intervals until just prior to admission, when they recurred every three to four days. The patient had constipation with the episodes, but otherwise had no significant gastrointestinal symptoms. At no time did he have diarrhea. Loss of weight occurred only during the last year of symptoms prior to laparotomy. Almost from the beginning, the patient had been given steroids as long as the symptoms lasted during the febrile episode. The examination gave entirely negative results. The only abnormal laboratory findings prior to operation were increased sedimentation rate (88 mm. per hour by the Westergren method), mild anemia, and slight leukocytosis. At operation, the spleen was found to be about twice normal size and mesenteric lymph nodes were enlarged. Biopsies of these nodes and of the jejunum revealed the typical findings of intestinal lipodystrophy.

Comment

We believe that exploratory laparotomy should be considered seriously in selected patients when thorough and repeated studies do not reveal the cause of an indeterminate fever. If a thorough, detailed history and physical examination reveal no helpful leads or positive findings, if all of the laboratory tests give no clues, if tissue cannot be obtained for study and diagnosis, and if the patient continues to look chronically ill and has a history of loss of weight, some anemia, and a high sedimentation rate, then one should think seriously of abdominal exploration. The basis for our advocacy of this procedure is the fact that the abdominal cavity and the retroperitoneal region cannot be examined adequately or visualized thoroughly with the available diagnostic procedures except by exploration. This is in contrast to other body systems, such as the central nervous system, the respiratory tract, or the genitourinary tract, where fairly precise examination and visualization are possible, so that one may say with some assurance whether disease is present as a basis for the obscure fever. Exploratory laparotomy should be considered as one of the steps in a planned study of selected patients with obscure fever.

In the selection of patients, care should be used to exclude those who have had the uncommon clinical syndrome of "periodic fever"[14] over a long period. In this syndrome the patient has febrile episodes that occur at intervals ranging from two days to six months, but usually from 7 to 28 days. Once the cycle has been set it generally remains the same. The episodes may recur for as long as 30 to 40 years and they may last for 12 hours to 10 days. The temperature may go as high as 105 F (40.5 C) and is usually accompanied by the systemic symptoms that go with episodes of high fever. The leukocyte count may be normal or increased. The sedimentation rate may be slightly increased with the attacks but is normal between attacks. These people have good health between attacks and manifest no loss of weight or anemia. They look well and have no other evidence of organic disease.

If abdominal exploration, perhaps as the last of a planned series of diagnostic procedures, does not reveal a diagnosis, then we will have done everything for the patient that it is possible to do. Therapeutic trials can be given subsequently with antibiotics or with other chemotherapeutic agents, or the patient can be sent home for further observation. Until abdominal exploration is done in these patients, we feel that all manner of therapy should be withheld except in certain selected patients who, one suspects, should have an adequate trial of antibiotic therapy first to see if some hidden infection can be brought under control.

Therapeutic trials are indicated in situations in which it is felt that a specific infection or specific disease entity is present. They are justified when repeated examinations have not led to a diagnosis and the patient's condition continues to deteriorate. One should be careful in the interpretation of the response that is obtained with a therapeutic trial. Bennett[6] has stated that a nonspecific response coincident with the administration of a drug can be very misleading. This has been our experience also. One should try to obtain unequivocal evidence of a diagnosis by tissue examination or cultures if at all possible before any therapy is given. Exploratory laparotomy should precede antibiotic or other drug therapy, if possible, in patients who are suspected of having organic disease. Bennett[6] has cited two excellent examples in which tuberculous peritonitis was felt to be present. In both instances other diagnoses resulted; autopsy revealed lymphosarcoma in one, and abdominal exploration showed cancer of the colon with perforation and localized abscess formation in the other.

Therapeutic trials should be carefully planned and carried out, and the results should be interpreted with caution. We have seen one patient with obscure fever in whom we could not make a diagnosis and who had a definite heart murmur which was thought to be of organic origin. Many consultants felt that the patient had endocarditis, and he was given a therapeutic trial with antibiotics. The temperature did not come down to normal during treatment with penicillin and streptomycin but did so on the 10th day after tetracycline was added to the therapeutic program. At postmortem examination a miliary granulomatous type of Hodgkin's disease was found in the liver, spleen, and some of the other abdominal viscera. The patient did have organic heart disease, but it was a congenital perforation of one of the mitral valve leaflets and was uncomplicated by any infection.

A recent review of treatment of pulmonary and pelvic tuberculosis at the Johns Hopkins Hospital indicated that treatment with either isoniazid or streptomycin and aminosalicylic acid causes lessening of fever in 80% of the patients within six days[6]; more than 95% responded by the third week, and it was concluded that treatment for one month constitutes a trial of therapy with antituberculosis drugs.

Our own experience with bacterial endocarditis in patients who present a rather typical clinical picture, except that organisms have not been cultured from the blood, is that the therapeutic re- [redacted] n of 10 [redacted] Gm. of [redacted] Gm. of [redacted] to 7 days and [redacted] orough trial of [redacted] bacterial endo- [redacted] include tetracycline [redacted] cover for possible gram-negative bacterial infections. If no response is obtained in five to seven days with penicillin and streptomycin, 3 Gm. of tetracycline in divided dosage should be added to the program for another three to five days. Failure of the temperature to come down with this regimen of [redacted] 10 [redacted] obscure fever in most instances.

Clinical reviews of fever of unknown origin give only passing mention to the value of laparotomy in patients with indeterminate fever.[16] Hand,[17] in a recent review of unexplained fever, stated, "More and more, we are resorting to abdominal exploration or diagnostic thoracotomy when other measures fail." This has been our practice also.

All patients with obscure fever should have x-ray [redacted]. When [redacted] und on x-ray examination, cholecystectomy should be carried out and the rest of the abdomen and the retroperitoneal region should be thoroughly investigated. Most observers would agree about this. There is some question, however, in the minds of many clinicians whether exploratory laparotomy should be performed when examination and investigation of the patient repeatedly give negative results. Some think the procedure is too radical; others prefer treatment with nitrogen mustard, x-rays, or cortisone in the hope that improvement will occur; and still others prefer continued observation and repeated investigation until the cause of the fever becomes obvious. However, when a patient has been ill for some time with obscure fever and comes to the physician with the hope that something may be found and his symptoms relieved, he should be advised to undergo exploration after thorough study if it is still thought that organic disease is present. These patients should not be treated with x-rays or nitrogen mustard before a definitive diagnosis has been made; such nonspecific treatment only serves to confuse the clinical picture further. The fact that a febrile reaction ceases after x-ray therapy or nitrogen-mustard therapy is not proof that the patient had a lymphoblastoma or some other lesion.

In approximately 80% of our series of 70 patients, something was found at operation. In 60% a definite diagnosis was made; in an additional 20% the disease was of a nonspecific granulomatous nature or it was a nonspecific infection; and in approximately 20% nothing was found.

In none of the eight patients with nonspecific granulomatous disease was there a history of allergy. Eosinophilia was noted in only one; that was the patient with caseating granulomatous abscess who had had two laparotomies. The granulomatous lesions apparently were limited to the abdomen only. Seven of the eight patients were well at the time of writing. The histological appearance of the biopsy specimen in several patients was consistent with a diagnosis of "sarcoidosis."

It was impossible to know the cause of the granulomatous disease in these eight patients. They could be presumed to have had benign, perhaps inflammatory, disease of some kind. However, the consistency with which all cultures gave negative results would tend to exclude bacterial infection, although previous antibiotic therapy in some of these patients may have rendered the cultures negative. The patient with the caseating granulomatous abscesses in the liver had a high eosinophil count. She had taken 1.25 mg. of conjugated estrogenic substances (Premarin) daily for years, and it was considered possible that this drug might have been antigenic in this patient, giving rise to a hypersensitivity granulomatous type of reaction. She was advised to take no antibiotics or other medicament postoperatively. She recently wrote that her fever gradually disappeared over a period of six to eight months and that she is now well. It is quite possible that these eight patients represent instances of hypersensitivity granulomatosis.[18]

It should not be forgotten that infection and malignant disease of the kidneys may be present even when the urographic appearance is normal. An excretory urographic examination should be one of the earliest tests performed in patients with fever of obscure origin. At laparotomy the kidneys should actually be visualized, not merely palpated. This point is illustrated by one of the two patients with malignant disease of the kidney as a source of obscure fever. On the first abdominal exploration the kidneys felt normal on palpation; at the second exploration four months later, after further urologic study, the renal carcinoma was found. In the original 200 cases of Kark and co-workers[19] in which needle biopsy of the kidney was performed, there were 5 cases of bacterial renal infection in which cultures of the urine gave negative results. These five cases represented problems of obscure fever. Appropriate antibiotic therapy was curative after diagnosis resulted from needle biopsy of the kidney. This raises the question of doing a needle biopsy of the kidneys before or at the time of each laparotomy to be sure that renal infection does not exist.

Summary and Conclusions

An analysis of 70 recent Mayo Clinic patients who had fever of obscure origin and who underwent abdominal exploration for purposes of diagnosis indicates that this procedure should be carried out when a planned investigation of such patients does not reveal a diagnosis. Patients who have had repeated episodes of fever, who continue to manifest debility and chronic illness, and whose disease is progressive should be considered for exploratory laparotomy. Evidence of continuing loss of weight, a high sedimentation rate, and progressive anemia in the absence of a definitive diagnosis should aid in the decision for exploratory laparotomy.

The data presented indicate that in approximately 80% of such patients something will be found at the time of exploration and that a precise diagnosis will be made in about 60%. Patients who have had only one prolonged bout of fever and whose condition is improving despite the previous presence of anemia, increased sedimentation rate, and loss of weight should not be subjected to exploratory laparotomy.

In approximately 20% of our cases abdominal exploration revealed indeterminate granulomatous disease or nonspecific infection, and in about 20% it was completely unrevealing. The operative risk in these patients is minimal; the postoperative morbidity is slight. No deaths occurred in this series. Exploratory laparotomy is frequently of real diagnostic value in selected patients with fever of obscure origin.

CONTROL OF INTRACTABLE PAIN IN ADVANCED CANCER BY SUBARACHNOID ALCOHOL BLOCK

Richard C. Hay, M.D., Takeshi Yonezawa, M.D.
and
William S. Derrick, M.D., Houston, Texas

Relief from otherwise intractable pain in the lower portions of the body can frequently be afforded by the subarachnoid injection of absolute alcohol. The technique here described is believed to give more predictable results and to cause less of the distressing complications (paralyses, paresthesias, and vesical and intestinal dysfunction) than do older methods. This method, involving the careful positioning of the patient and other precautions to limit the action of the alcohol to the dorsal nerve roots, was applied in 106 patients with hopeless malignant disease. The results were classed as good in 53 and fair in 35. Ten spinal cords were examined at subsequent autopsies, and the most constant finding was demyelinization of the dorsal roots of the spinal nerves. The effects extended peripherally to the dorsal root ganglia and centrally into certain tracts within the cord. The abolition of pain was not always permanent, especially since metastases sometimes appeared in distant parts, but some patients were completely relieved for eight months or more.

In the constant search for a method to relieve intractable pain in advanced malignant disease, many agents have been used. This communication will present the clinical results of 175 subarachnoid alcohol segmental blocks, the histopathology of 10 spinal cords after this procedure was done, and a brief review of the neuroanatomy concerned.

The first report of the use of subarachnoid alcohol for pain relief was by Dogliotti [1] in 1930. Several other favorable reports [2] were published during the following several years, all concerned with the use of this technique in the treatment of intractable pain in malignant conditions. The majority of the injections were accomplished in the lumbar interspaces and more often than not resulted in rectal and bladder incontinence, motor paralysis of the lower extremities, and poor pain relief. The explanation of these unfortunate complications is that the nerves in the lumbar area are mixed nerves, carrying both sensory and motor impulses. Hence, if alcohol is introduced into this area, both modalities will be disturbed. Thus, the procedure described by Dogliotti never has gained widespread use or acceptance because of the unpredictability of its effects and the occurrence of distressing complications, that is, muscle paralyses, bladder and intestinal disturbances, and painful paresthesias.

From the Section of Anesthesiology and the Department of Pathology, the University of Texas M. D. Anderson Hospital and Tumor Institute.

Neuroanatomy

A brief description of a typical spinal nerve [3] will show the anatomic basis for this procedure. Each spinal nerve is composed of two roots: an anterior (ventral, motor, efferent) and a posterior (dorsal, sensory, afferent). The posterior root is the larger of the two. It is composed of multiple rootlets which arise from the posterolateral sulcus of the spinal cord. These unite to form two bundles which join the spinal ganglion. After leaving the ganglion, the posterior root joins the anterior at the intervertebral foramen. Both anterior and posterior roots are covered by pia, arachnoid, and dura. The two roots pierce the dura separately, and each root receives an investment of this membrane which is continuous with the epineurium of the combined nerve (fig. 1).

The roots of the spinal nerves below the third cervical vertebra run obliquely downward and laterally. This downward angle increases progressively throughout the length of the cord so that at its termination at the interspace of L-1 and L-2 the roots are parallel to the long axis of the cord. It is therefore practical to interrupt the dorsal roots at their cord level rather than at their vertebral level (fig. 2). Most commonly the cord terminates at the body of the first lumbar vertebra, occasionally at the upper portion of the body of the second lumbar vertebra. For practical purposes, the L-1 and L-2 interspace is considered the level of termination. The dorsal roots are accessible for blockade at specified interspaces above the lumbar area only.

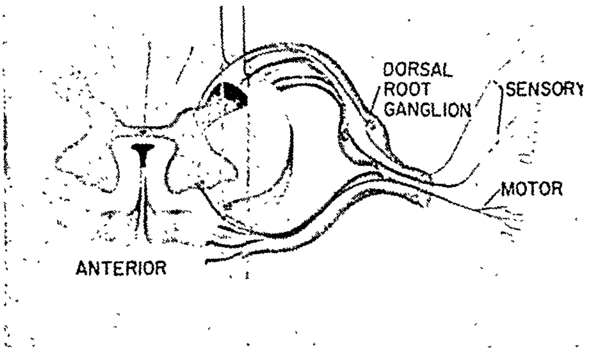

Fig. 1.—Diagram of typical spinal nerve.

The dorsal root fibers [4] subserving tactile, thermal, pain, and proprioceptive sensations enter into synaptic relations within the gray matter of the cord, not only with secondary sensory neurons which relay impulses toward the cerebral cortex but also with association and commissural neurons which are connected with motor neurons and are concerned with spinal reflexes. With this arrangement of ascending, descending, crossed, and uncrossed pathways, it is apparent that pain impulses may be appreciated by any one of several avenues of ingress at multiple segmental levels.

There are two ascending tracts of importance to this discussion: the lateral and ventral spinothalamic tracts. Briefly, these tracts are as follows:

In the ventral spinothalamic tract, the unipolar cell body of the first order neuron is in the spinal ganglion. At varying levels, synapses are made in the columna posterior with the second order neuron. The cell body of the second order neuron is in the posterior gray column. It sends an axon across the median plane to the ventral spinothalamic tract in the opposite anterior funiculus and thence to the thalamus. From the thalamus, axons of the third order neuron go by way of the thalamic radiation to the somatesthetic area of the cerebral cortex.

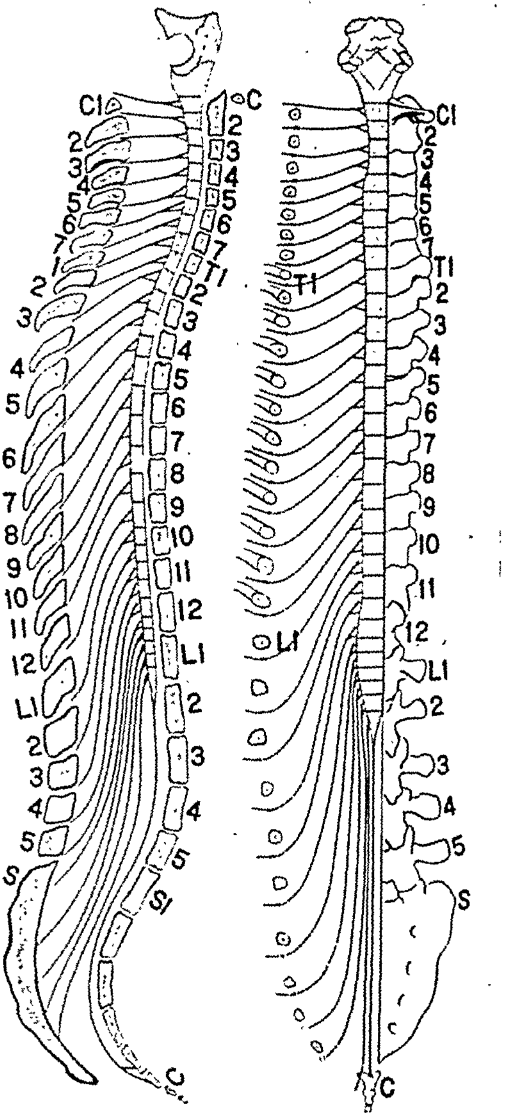

Fig. 2.—Roots of spinal nerves.

In the lateral spinothalamic tract, the unipolar cell body of the first order neuron is in the spinal ganglion and sends a process to the skin and to the deeper tissues. The central process immediately terminates in the cord. The second order neuron is located in the posterior gray column. The axon immediately crosses the medial plane and ascends in the lateral spinothalamic tract to end in the posterolateral ventral nucleus of the thalamus. From the posterolateral ventral nucleus of the thalamus, the third order neuron conveys thermal and painful impulses by way of the thalamic radiation to the somatesthetic area of the cerebral cortex.

Technique

The technique of subarachnoid alcohol block[5] is little different from that normally used for spinal anesthesia. The principal difference between the two is one of position of the patient. It is far preferable to use a standard operating table with its inherent mechanism for "flexing" the table. The patient must be placed on the table with the side to be blocked uppermost and the site of needle insertion directly over the "break" in the table. The table is then flexed so that the needle site is at the peak of the bend in the thoracic curve. That is, the head and hips are always lower than the site of injection. The body is then rotated anteriorly approximately 45 degrees. The patient is securely fastened in this position. If a bilateral block is desired, the patient is placed in the prone position with the peak of the curve made by the flexed table at the needle site as before. Each of these two positions brings the posterior roots to the highest point in the dural tube (fig. 3).

After the positioning, the subarachnoid puncture is made in the routine manner. One must be absolutely certain that the bevel of the spinal needle is lying freely within the subarachnoid space and not in the peridural space or the cord itself. It may be necessary to aspirate cerebrospinal fluid instead of waiting for it to appear at the hub of the needle, since, occasionally, when the patient is in the prone position the spinal fluid pressure is too low for free flow. The actual injection of the absolute alcohol must be slow and deliberate. The patient must be warned prior to injection that he may feel exquisite burning, warmth, or sharp pain in the segment involved. This sensation usually lasts a few seconds at peak intensity and then fades away during the next few minutes. The area of paresthesia indicates the segment blocked, of course, and is a good index of the level of blockade.

If there are multiple segments involved, it is more desirable to use two or three needles at successive interspaces than to inject a large volume of solution through one needle. If the latter is done, motor paralysis may result, since the large volume of alcohol may diffuse anteriorly to involve the anterior roots. After the alcohol has been injected, the patient must remain in the position for at least 45 minutes to allow the alcohol to become fixed to the neural tissue and to be diluted by the spinal fluid. The patient may then be turned to the supine position and returned to his bed, where he should remain flat for two hours.[5]

After the block, the evaluation of the degree of pain relief is a difficult task. The enthusiasm of the operator for the procedure may cause interpretation of more pain relief than is actually present. The best indexes of pain relief are the observations of the nurses and the patient's family. Often, the patient will tell them much more than he will tell the doctor. The block may be repeated after two days have elapsed if there is no change in the pain pattern.

Since many of these patients have been receiving narcotics for varying periods of time and are addicted, this factor enters into the evaluation of the results of the block. Many patients will deny relief, even though it is present, in order to have an injection every four hours. Under no circumstances should they be abruptly cut off from narcotics, but the dosage should be gradually reduced to approach homeopathic levels or even none.

The duration of pain relief is variable. Some have complete relief for eight months or more, while some only for a few weeks. The usual duration of relief is three to four months. An occasional patient will have no change in his pain pattern at all after the block. When this occurs, it usually means the alcohol did not reach the posterior root in sufficient concentration to interrupt impulses. In this case, the procedure should be repeated. It is a rare patient who does not have some alteration of pain pattern under these circumstances.

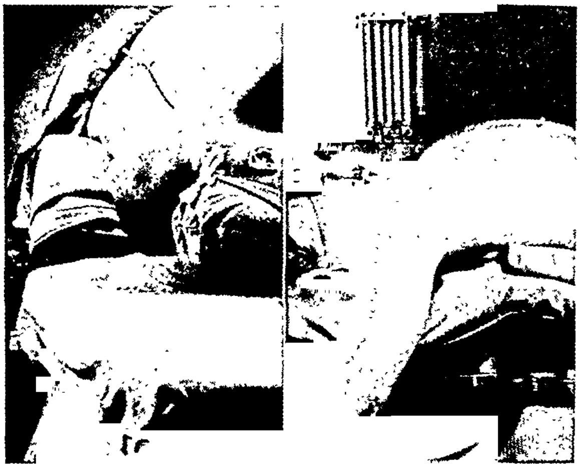

Fig. 3.—Position of patient for *(left)* block of left side and *(right)* bilateral block.

Complications are infrequent if the rate of injection, position of the patient, site of puncture, and technique are carefully observed. Headache and meningismus are rare and when they do occur are quite self-limited. The two most serious complications are those of muscle paralysis and bladder or rectal incontinence. The former is avoided if careful attention is paid to the position and rate of injection so that the alcohol is confined to the posterior root. Bladder incontinence, when it occurs, is usually transitory in nature and is handled easily with an indwelling catheter for a few days. Occasionally, there is marked proprioceptive sensory loss in the lower extremity which results in difficulty in walking. Again, this is a short-term loss and usually clears in seven to ten days.

Clinical Results

From June, 1956, to June, 1958, 106 patients received 174 subarachnoid alcohol blocks, with good results in 53 patients (50%), fair in 35 (33%), poor in 11 (10%), and no result in 7 (7%). Pain relief has been classified as good when complete relief is noted; fair, relief but with continued occasional narcotic demand secondary to addiction; poor, less pain but narcotics still needed; and no result, no pain relief at all.

In this group of 106 patients, there were only three complications of note. One was urinary incontinence, lasting four days, which necessitated the use of an indwelling Foley catheter. The other was a left deltoid muscle paralysis after a right subarachnoid alcohol block at the C-6 and C-7 interspace. This patient was known to have cerebral metastasis at the time, and death occurred two months after the procedure. The third was a paraplegia on the third day after a unilateral left block at the C-7 and T-1 interspace. This patient underwent a decompression laminectomy of T-1 to T-4 inclusive and was found to have a massive extradural metastatic carcinoma. At the time of the block, the needle apparently caused enough trauma in passing through this tumor to cause hemorrhage into it, which gradually compressed the cord at that level. This patient died three weeks after laminectomy, and at autopsy metastatic disease was found throughout the mediastinum and paraspinal area from C-5 to T-7. In four other patients, there was marked proprioceptive loss in the ipsilateral extremity. All of the latter cases resolved themselves without active treatment other than the patients' initiative in moving around.

Pathology

Ten spinal cords were obtained at autopsy. The time after alcohol block varied from three days to nine months. There were six females and four males, ranging from 8 years to the upper 70's, and each was in the terminal phase of malignant disease. In four instances four or more blocks had been done, while the remainder had a single procedure.

Demyelinization of the posterior roots, either unilateral or bilateral, was by far the most constant and outstanding finding. In three instances, degeneration of the axis cylinders was also encountered in the posterior root. Posterior root ganglions near the injected level showed moderate swelling and chromatolysis. The associated posterior roots showed severe demyelinization (fig. 4).

Within the cord itself, the most regularly affected areas were the fasciculus dorsolateralis (Lissauer's tract) and the posterior funiculus. The fasciculus dorsolateralis showed some degree of demyelinization in eight cases, while the posterior funiculus was involved in all but one. In many, the change was small and was represented by a narrow demyelinated band in the lateral part of the cuneate fasciculus at the level of the injection only. In others, there was much more extensive demyelinization occupying the entire thoracic column at the injection site and extending cephalad deviating medially in the cord. Below the site of injection, cells of Clarke's column were affected as were those of the posterior and lateral gray columns.

In brief, the above findings were consistent in all the cords studied. In eight additional cords, these findings were also noted. A more complete and detailed report will be published elsewhere on this aspect of subarachnoid alcohol block.

Comment

Constant pain extracts a terrific toll, both physically and emotionally, affecting not only the patient but those around him. The majority of patients in this study were physically incapable of withstanding another operative procedure or refused further operative intervention. In all cases, these patients had nothing to look forward to except a miserable, painful existence made somewhat easier by the liberal use of narcotics.

The most difficult aspect of any procedure for relief of pain is the assessment of the results therefrom. Patients with malignant disease not only are beset by physiopathological problems but also sustain a tremendous emotional upheaval as a result of the fact that they have a very serious disease which will probably be fatal to them. If these two facts are coupled with the overwhelming economic crises facing them in the course of their disease, it is not too difficult to see why they are unable clearly and rationally to evaluate discomfort relative to pain. These three factors, plus normal fluctuations in severity of pain, the difficulty of measuring pain accurately, and the inherent enthusiasm for the procedure in those attempting to alleviate pain make the degree of pain relief difficult to evaluate.

By its very nature, cancer is prone to spread by both a contiguous and distant manner. This means that pain may come from many areas at once with one locale giving more severe pain than others. Also, it means that one source of pain may be successfully blocked while a few weeks later another metastatic focus may be the source of pain at that time. With this in mind, it follows that any purely scientific criteria for evaluation of this type of pain relief are probably not suitable. When relief was obtained with narcotics, morphine, meperidine (Demerol) hydrochloride, and similar drugs were used. Many patients who experienced pain relief

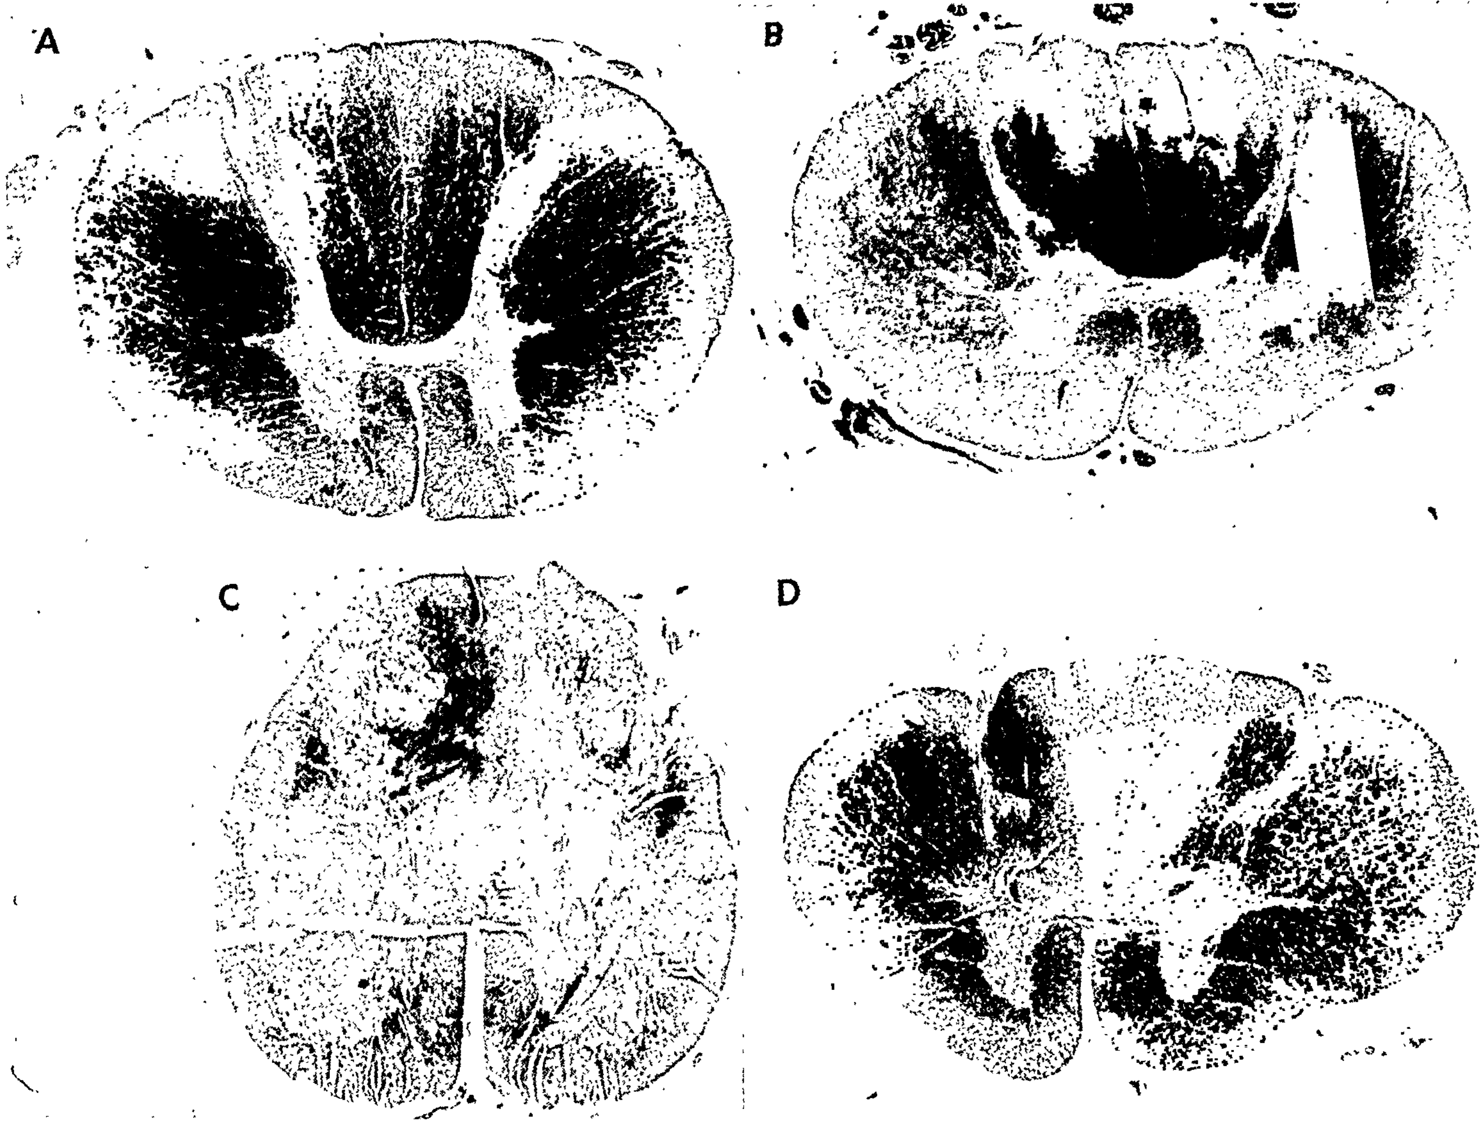

Fig. 4.—*A*, demyelinization of right dorsal root and adjacent wedge-shaped area of spinal cord at T-4. Such changes are considered to be result of direct contact of alcohol on cord. *B*, necrosis and demyelinization of dorsal part of posterior funiculus bilaterally (T-8). *C*, massive softening in left gray column and demyelinization in posterior and lateral white columns. It is believed that this resulted from accidental deposition of alcohol within cord. *D*, ascending degeneration in posterior funiculus at T-2. There was demyelinization of dorsal roots and lateral parts of posterior funiculus at T-3.

from the block needed analgesics, such as aspirin, a combination of acetophenetidin, aspirin, and caffeine (Empirin compound), and a preparation containing aspirin, aluminum glycinate, and magnesium carbonate (Bufferin), for complete comfort, while others who were receiving large doses of morphine or meperidine could receive dramatic reductions in dosage to one or two injections daily. The poor-result patients were those who had some alteration in pain pattern but who still needed a narcotic regularly, albeit in reduced amount, for comfort.

Summary

Subarachnoid alcohol block was performed in 106 patients with intractable pain due to malignant disease. There was a definite change in severity of pain in 83% of the patients, with 50% obtaining complete relief and 33% partial relief.

In 10 spinal cords examined at autopsy, the most constant finding was demyelinization of the posterior roots plus moderate swelling and chromatolyses of the posterior root ganglions. There were no complications of a lasting nature in any of the 106 patients in this series. Subarachnoid alcohol block is a worthwhile procedure in patients with intractable pain due to malignant disease. It is inexpensive; it can be performed by any skilled or well-trained anesthesiologist or neurosurgeon; and in such hands there will be few complications. It appears that subarachnoid alcohol block deserves a place in the physician's armamentarium in the constant war against the intractable pain of advanced malignant disease.

MICROBIOLOGICAL TERMINOLOGY.—All nomenclatural codes agree that the scientific name of a species is made up to two parts. . . . The first component is a proper noun, in the singular number, which is the name of the genus in which the species is included. Botanists and bacteriologists agree that the second component is to be termed a specific epithet, but the zoologists have somewhat confused other biologists by their recent decision to call the second component the specific name. Why are other biologists confused? Because in bacteriology and botany the designations "species name" and "specific name" are synonymous. In zoology they are not, the specific epithet of the bacteriologist is the specific name of the zoologist. It should be clear that the specific epithet is not the name of a species, it is an explanatory word or phrase limiting the application of the generic name to a single species . . . [An epithet] . . . may be a single word which in some way defines or limits or modifies the meaning of the generic name or it may be a single phrase consisting of two or more words which together convey a single idea, but which do not separately modify the generic name. The codes of nomenclature specify clearly that a specific epithet may be one of three types: 1. An adjective (simple or compound) which directly modifies the generic name, and agrees with it in gender, number, and case. As Sarcina lutea, the yellow Sarcina. 2. A noun in the genitive modifying the generic name. It need not agree with the generic name in gender or number. As Escherichia coli, the Escherichia of the colon. 3. A noun in apposition with the generic name. It agrees in case with the generic name, but need not agree in gender. As Xanthomonas prunicola, Xanthomonas the plum dweller.—R. E. Buchanan, Microbiological Literacy, *Bacteriological Reviews*, September, 1958.

CLINICAL NOTES

STOMATITIS AND PROCTITIS AS MANIFESTATIONS OF MEPROBAMATE IDIOSYNCRASY

Jonas Brachfeld, M.D.
and
E. Cooper Bell, M.D., Philadelphia

The incidence of serious untoward reactions to meprobamate must be small in view of the widespread use of this drug. The following case is reported because it is believed to represent the first recorded instance of such a reaction to meprobamate. Furthermore, it represents a rare type of reaction to any drug.

Report of a Case

A 51-year-old woman was admitted on June 23, 1958, to *Woman's Hospital, Philadelphia, because of a myocardial* infarction. She was treated in the conventional manner with bed rest and bishydroxycoumarin (Dicumarol); in addition, her previous medication with chlorothiazide, 0.5 Gm. daily, and digoxin, 0.5 mg. daily, was continued. Pentobarbital was given nightly, but, starting on July 8, chloral hydrate was substituted. Because of continued restlessness during the day, as well as sleeplessness, therapy with meprobamate, 400 mg. given four times a day, and secobarbital and phenobarbital given at bedtime was started on July 11. The patient received two tablets of meprobamate on that day, and the next morning she remarked vaguely to a house officer that she was "allergic to tranquilizers" and that her mouth felt sore. Meprobamate therapy was therefore discontinued, but that with the other drugs was maintained. A few shallow ulcers were noted on her oral mucosa on July 11. By July 14, this had progressed to extensive sloughing ulceration of the mucosa of inner cheeks, tongue, and palate. The patient complained of severe soreness of her mouth, to the point that she had difficulty swallowing liquids, as well as general malaise and severe itching and burning of the anal area. Her temperature rose to 100.4 F (38 C); she appeared acutely ill. Her cervical lymph nodes were swollen and tender. The dental consultant felt that the lesion was typical of necrotizing ulcerative (Vincent's) stomatitis but that acute moniliasis and herpetic stomatitis should be ruled out.

On July 15, she noted one episode of frank anal bleeding ("about 2 teaspoons" of bright blood). She had no other gastrointestinal signs or symptoms. Because of her cardiac status, it was thought wise to postpone sigmoidoscopy and barium studies.

At this point additional history revealed the nature of the patient's previous meprobamate reactions. In July, 1957, she had been given meprobamate for the first time. She took a total of 400 mg. of meprobamate, and within 24 hours she had extensive blistering of mucosa of the lips and tongue, as well as severe itching and burning in the oral area. She was assured then that this was unrelated to the drug. Apparently syphilis was suspected, but darkfield examination and serologic testing gave negative results. In March, 1958, after ingestion of a single tablet of meprobamate, her mouth "felt severely swollen" but this gradually subsided. An extensive history failed to disclose stomatitis on any previous occasion, intolerance to other drugs (including barbiturates) or foods, or any typical allergic symptomatology.

In view of this history, cortisone acetate medication was started, 50 mg. by mouth every four hours. This was done with some trepidation lest an infectious process be aggravated by this therapy. However, the patient improved markedly in 24 hours; her fever and adenopathy subsided. The extensive ulcerations gradually improved in the ensuing days, during which time cortisone dosage was slowly tapered off and then discontinued. Therapy with the barbiturates and the cardiac drugs was continued during this whole period. Microscopic and darkfield examination of a mouth swab on July 14 were later reported as negative for fungi and Vincent's organism, and only streptococci and staphylococci could be cultured from it.

Comment

The problem of meprobamate idiosyncrasy has been thoroughly reviewed recently by Charkes.[1] He points out that about 1 patient in 200 may respond to an initial administration on meprobamate with an anaphylactoid response. In a series of 113 cases of meprobamate idiosyncrasy that he collected from the literature, a cutaneous reaction appeared as early as 15 minutes or as late as one week after the initial dose. The rash was erythematous, maculopapular or urticarial, or a combination of these. Systemic symptoms were also present in a number of cases. Of eight reported skin tests (patch or scratch), six showed completely negative findings. A patch test also showed negative findings in our case. An oral mucosal test may be more informative, but it requires some experience for performance and interpretation.[2] A "latency" period, arbitrarily set at two weeks after the first dose, may serve to separate cases of true allergy from mere idiosyncrasy.[1] Antihistaminics have not resulted in dramatic relief in these conditions. Steroid therapy often has been helpful. In our case, steroid medication produced marked relief from both the generalized "toxicity" and local reaction. Levan [3] states that the cutaneous reactions of meprobamate are characterized by (1) their early appearance (sometimes as early as 15 minutes); (2) a severe erythematous rash, at times purpuric, tending to be particularly severe in the groin; and (3) associated marked weakness, faintness, and transient but recurrent syncope.

From the Medical Division, the Woman's Hospital.

To our knowledge, no case of meprobamate idiosyncrasy with mucocutaneous manifestations consisting solely of stomatitis and/or proctitis has been reported. This reaction must be extremely rare in view of the tremendous use of this drug. Two major manufacturers had no knowledge of such type of reaction.[4] In view of this rarity, local and other etiological factors should be carefully considered before a case of stomatitis or proctitis is attributed to the coincidental intake of meprobamate. On the other hand, Charkes[1] emphasizes that with the administration of a test dose the second reaction could be much more severe than the first. This was inadvertently demonstrated in our case. If it is imperative to give such a test dose, no more than a small amount (50 mg.) should be tried.

Summary

A case of stomatitis and proctitis developed on several occasions after administration of meprobamate. In the last instance the reaction was severe, progressed in spite of withdrawal of the drug, and responded to cortisone therapy.

BUCCAL AND SUBLINGUAL ADMINISTRATION OF HEPARIN POTASSIUM (CLARIN)

STUDIES OF PLASMA TRIGLYCERIDE LIPOLYSIS AND HEPARIN LEVELS

Hyman Engelberg, M.D., Los Angeles

The discovery of the clearing of alimentary lipemia after the injection of heparin[1] and the demonstration of long-term efficacy of intermittent, parental administration of heparin in reducing the anticipated mortality of elderly patients with severe coronary atherosclerotic disease[2] aroused interest in the possible role of this physiological substance in fat transport and in its use as prophylactic therapy in hyperlipemic and hypercholesterolemic states. If heparin were effective by mouth, it would probably be the drug of choice in all patients with clinically diagnosed atherosclerosis. Therefore, the original report[3] of the absorption of sublingually given heparin attracted widespread attention. Unfortunately, these findings were not confirmed.[4] Subsequently, Italian authors reported a 20% absorption of buccally given heparin with an effect on lipoproteins but not on coagulation.[5] Recently, clarification of postprandial lipemia after the use of heparin potassium tablets was demonstrated as an exhibit,[6] and the product used (Clarin Linguets) has been subsequently released on the market.

The use of serum optical density levels as an index of the rate of removal of fats from the blood stream after standard fat meals affords suggestive but not conclusive results, since variations in intestinal absorption may affect the findings, and optical density may decrease without a concomitant reduction of the lipid content of the plasma. Moreover, when medicaments are given which may contain mucinous substances, the measurement of lipemia by optical techniques is entirely inadequate, since mucins may clear lipemic plasma through physical effects without fat lipolysis or fat removal taking place.[7] Accordingly, the experiments reported in this communication were designed to avoid these pitfalls by evaluating triglyceride lipolytic activity in vitro and by measuring plasma heparin potassium content directly before and after use of the drug.

Method of Study

Twenty-one subjects were studied. Blood was drawn in the fasting state and 45-60 minutes after the buccal or sublingual administration of the heparin potassium tablet, containing 1,500 units of heparin potassium (when it was almost all dissolved). In several instances a third blood sample was taken one hour later. Fasting blood was used since it has been shown that after heparin is given the lipemia clearing factor (lipoprotein lipase) is inactivated during the fat-splitting process.[8] Therefore, if neutral fat had been available as substrate in the blood, and in vivo lipolysis consequently occurred, small amounts of enzyme activity after administration of heparin could be missed by in

---

From the Division of Laboratories, Cedars of Lebanon Hospital.

vitro techniques. In nine subjects, a small dose of heparin was given intravenously after the second blood sample was taken and blood was again withdrawn in 10 minutes. Oxalated plasma was separated in a refrigerated centrifuge and lipemia clearing and lipolytic activity immediately determined with use of coconut oil and ultracentrifugally separated human low-density lipoproteins as fat substrates, according to previously described techniques.[9] In 13 subjects the plasma heparin potassium content was extracted and measured [10] before and after heparin potassium administration. The Lee-White method of determining clotting time was used on all blood samples.

Results

The results of the plasma lipemia clearing and lipolytic activity studies are shown in table 1. It is apparent that triglyceride splitting with release of fatty acids may occur without any evidence of clearing of coconut oil substrates. Therefore, the most sensitive and significant findings are shown in the last column of the table. In five subjects (cases 1, 2, 3, 7, and 13) there was evidence of more lipoprotein lipase activity after the heparin potassium administration than before, although in only three of the five was it of substantial proportions. In all seven subjects given 2-16 mg. of heparin potassium intravenously and in one of two given 1 mg. intravenously, increased clearing and lipolytic activity occurred. The next to the last column is included since it was possible that lipolysis occurred in the test tube as soon as lipoproteins were added and that it therefore might not be found during the one-hour incubation period. Thus, the substantially increased control fatty acids after the drug was given in the patients in cases 4, 10, 11, and 15 may indicate the presence of postadministration enzyme, although this is not certain. In summary, there was definite evidence of heparin potassium absorption and consequent substantial fat-splitting activity in three subjects and possible trace activity in six others after use of the tablets. It is of interest to point out that the patient in case 16 shows a clear example of nonlipolytic clearing and that the increased clearing without increased fat-splitting seen in the patients in cases 12 and 19 after the drug was given may represent the same phenomenon.

Table 2 presents the results of the heparin potassium assays in 13 subjects. The method has a ± 15% deviation from the mean. Thus, there is definite evidence of heparin absorption only in the patient in case 7. In contrast, the marked increase in the patient in case 21 after 2 mg. of heparin potassium was given intravenously is obvious. It is apparent that the method is not sufficiently discriminating to measure the small amount of heparin that must have been absorbed in the patients in cases 1 and 3, although the increase was shown in that in case 7. Nevertheless, since 2 mg. (200 units) given intravenously resulted in a 50% elevation (5.5 units %) in the circulating heparin potassium level, it would appear that less than 100 units (of the 1,500 units in the tablet) was present in the blood at the height of tablet's dissolution even in patients who showed lipolytic activity.

---

*Measured in Coleman Jr. spectrophotometer at 700 mμ every 10 minutes for one hour at 25 C.; 1 ml. of plasma + 0.1 ml. of 1% coconut oil (Ediol).

†5 ml. of plasma + 1.0 of ml. human low-density lipoproteins incubated at 37 C for one hour; aliquots analyzed every 15 minutes.

The results of the clotting time determinations are not shown, as no definite anticoagulant activity was found after administration of the heparin potassium tablets.

Comment

In view of the difference between the findings in the present study and those previously presented,[6] it is worthwhile to discuss possible criticisms of these experiments and the in vitro technique used. It may be argued that the effect of sublingually given heparin is delayed in some manner. However, it is reasonable to believe that absorption would be maximal when the tablet was fully dissolved. Furthermore, although the results were not shown in the table, in several instances a third blood sample was also taken one hour after the tablet had melted. The results were no different than in the first post-tablet test. Furthermore, it is possible that ultracentrifugally separated low-density lipoproteins are not as easily acted on by the postadministration factor as natural in vivo chylomicrons. However, the same lipoproteins were rapidly split by blood plasma drawn after 2 mg. of heparin was injected intravenously, thus proving their adequacy as a fat substrate. It thus is more likely that the discrepancy in the results is due either to the nonlipolytic fat-clearing action of other mucinous polysaccharides[11] or to the failure of the original investigator of heparin potassium[6] to use placebo tablets in his control observations. The tablets were composed of crude heparin, not highly refined, and probably contained mucins similar to heparin in basic structure. The failure of larger doses of sublingually given heparin to enhance the lipemia-clearing effect[12] or to result in any anticoagulant activity is further evidence against any substantial absorption by this route. It has been shown that, except for minimal doses below 3 mg., there is no support for the view that the amount of heparin required to influence the clotting mechanism is greater than that required for lipemia clearing.[13]

*Average of duplicate determination.

†Level was 17 units % after intravenous administration of 2 mg. of heparin potassium.

Heparin potassium, in the present study, was absorbed in doses large enough to produce substantial amounts of fat-splitting enzyme in only 3 of 21 patients—possibly trace amounts in another 6 subjects. In 12 of the 21 there was no evidence that heparin potassium had penetrated the mucosal barrier. Thus, from the practical standpoint, this route of heparin administration is uncertain and inadequate. Even if 20% of buccally given heparin were absorbed, as has been stated,[5] this mode of administration would be extremely wasteful. Furthermore, it is a long step from the clinically demonstrated beneficial effects of large doses of injected heparin in severe atherosclerotic disease[2] to the unproved virtues of minimal lipemia clearing.

Summary

The effect of heparin potassium tablets (Clarin Linguets) has been evaluated in 21 subjects by in vitro measurements of lipolytic activity and by determination of plasma heparin potassium levels. In 3 subjects there was moderate absorption of the heparin potassium, in 6 possibly trace absorption, and in 12 no evidence of absorption of buccally given heparin potassium. These results indicate that orally given heparin potassium tablets are ineffective in 85% (18 of 21) of patients and that parenterally given heparin should be used when this type of therapy is indicated in patients with atherosclerotic disease.

ASPIRATION OF AMNIOTIC FLUID OF THE PERINATE

NEW CONCEPT OF AN OLD DISEASE

Robert P. Barnett, M.D., Spokane, Wash.

Obstetrics has advanced to the point where the maternal mortality is less than 1%. It is both amazing and shameful to find an unchanged perinatal morbidity and mortality during the first 7 days of life in the last four decades.

Most of the literature on atelectasis and hyaline membrane disease in the perinatal period is concerned with the secondary chemical causation. Just as much is concerned with treatment of lung pathology, cardiac failure, elevated pCO_2 levels, anoxemia, and cerebral anoxia of an elective section of the premature infant and the infant of a diabetic mother.[1] Very little information has been offered concerning primary mechanical etiology and its immediate treatment.

At the risk of being practical, I believe the realist has the proper answer. How can one hope to bypass with oxygen the alveoli and/or bronchi and bronchioles two hours or later after birth? Treatment should be directed to the immediate care of the perinate (infant at birth)—not two or more hours later. By that time the amniotic fluid is well fixed in the alveolar walls and the bronchial tree.

In the full-term baby delivered by section, when the mother has had no labor, it is possible to aspirate from the stomach and tracheobronchial tree from 30 to 60 cc. of amniotic fluid with a soft rubber catheter. It is interesting to note that, from the average full-term infant delivered per vaginum, approximately 5 to 15 cc. of amniotic fluid can be obtained in the same way.

Therefore, the first recommendation to reduce morbidity and mortality in the perinate would be routine aspiration of the stomach contents with intermittent compression of the abdomen. A soft rubber catheter introduced two or three times will suffice. Tracheobronchial aspiration should not be considered routine but should be left in the hands of those who are experienced.

A simple method used by many physicians is recommended and can be described as follows: While awaiting placental expulsion and after gastric aspiration, the physician can introduce an infant laryngoscope into the oropharynx and gently lift the epiglottis. Then, with exposure of the trachea, the soft rubber catheter can be placed in the hypopharynx and a nurse can apply gentle artificial respiration on the anterior chest wall while the physician aspirates the amniotic fluid as it presents itself in the hypopharynx and the trachea. This is especially applicable to the premature infant because of injury to the trachea, even with a soft rubber catheter, and the time consumed by tracheobronchial aspiration in these weak infants.

The second recommendation, and I believe an imperative one, is that the infant, during the perinatal period (15 days), should be in the supine position only when the diapers are changed and in a few other exceptional cases—all should be done under close observation. This is particularly true during the first 3 days of life. In the nursery for newborn infants, thousands of times physicians and nurses have "just accidentally" seen an infant cyanotic and gasping while lying in the supine position. It should be mandatory that all infants be changed from side to side and to prone positions frequently. This also applies to the premature infants who appear to tolerate the prone position.

In a moribund perinate the head up or head down position in the nursery can be considered dangerous. There is great risk of the head falling

---

From the Pediatric Service, St. Luke's Hospital.

on the anterior chest wall and occluding the airway. However, in the healthy full-term baby, head up or head down positions should be left to the discretion of the individual physician.

Elective section mortality remains at 5 to 10% over the United States and has not been altered in the past 10 years. The incidence of cerebral palsy due to anoxemia and cerebral anoxia remains unchanged.

We will find that the primary mechanical etiology of aspiration of amniotic fluid in the newborn infant should receive prompt attention and treatment, instead of treatment of the secondary complications. This late treatment will only serve to continue the present situation.

With these simple delivery room and nursery techniques, carried out as a routine, we can reduce the infant morbidity and/or mortality by 50% in any of our general hospitals.

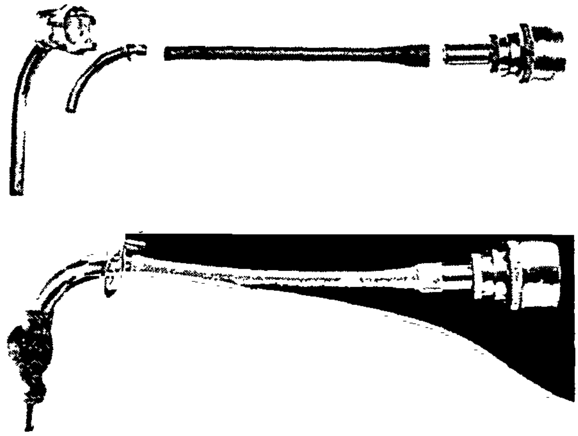
RESPIRATOR TRACHEOTOMY TUBE

William J. Loeb, M.D., Cleveland

Any general hospital treats patients who require respiratory assistance for reasons ranging from intracranial disease or injury with central respiratory depression, excessive drug intake, thoracic injury, or pulmonary insufficiency to unidentifiable causes. The problem involved is not one of mechanical airway improvement alone but also one of insufficient central respiratory stimulus. In coping with this problem a modified tracheotomy tube has been in use which in my experience has provided added control of respiratory exchange to tide the patient over a critical period until he can resume adequate respiration without assistance.



Top, component parts of tracheotomy tube. *Bottom*, assembled tube and fittings.

The use of a respirator with the familiar naso-oral mask is difficult because it precludes airway aspiration. Tracheotomy alone may not be enough because artificial respiratory control cannot be well maintained unless a closed system is provided. The tube which we have used (see fig.) consists of a cane-shaped tracheotomy tube made ⅜ in. (0.96 cm.) shorter than standard. The inner cannula is provided with a ⅜ in. extension beyond the base plate. To this a fairly stiff rubber tube is connected, at the other end of which a standard slip fitting is provided. This may be connected with a respirator. An inflatable rubber cuff (see figure) as is used in anesthesia is placed around the outer cannula. Inflation of this provides an airway which is completely under respirator control, avoiding leaks.

The flexibility of the tube placed between the inner cannula and the slip fitting permits some motion by the patient without disconnecting the slip joint from the respirator. Hitherto it has been difficult to use the respirator connected directly to the tracheotomy tube but this inner cannula and flexible tube may be quickly removed for tracheal suction and replaced without loss of significant respiratory exchange.

These tubes, in sizes 1 through 7, have been used successfully at Mt. Sinai Hospital. There has been minimal irritation of the trachea, even in patients who are conscious.

10300 Carnegie Ave. (6).

Careers in Health

Are there any budding orthoptic technicians among the students in your local high school? Probably not—a career as an orthoptic technician is so new that few have heard of it. This is one of the reasons that recently led the Connecticut State Medical Society to inaugurate "Connecticut Health Careers."

Aided by its Woman's Auxiliary and other health organizations, the society's program is designed to acquaint high school students with career opportunities growing out of advances in medical research, hospital practice, and patient care.

The nucleus of the program was the Auxiliary's past efforts in advancing nursing as a career. When the current project was begun last fall on an experimental basis in a few schools, it showed such promise that it is now being activated on a statewide basis. It covers as many as 50 career occupations. Speakers, films, field trips to hospitals and laboratories, and a variety of publications are ingredients of the program.

Cooperating groups include the Connecticut Hospital Association, the Connecticut League for Nursing, the Connecticut Society of Pathologists, the American Registry of Technicians, the Connecticut Public Health Association, and the A. M. A.

Dr. Harry C. Knight, chairman of the Society's committee to develop the project, is enthusiastic about early results. He said: "We have found a welcome interest, and the future looks bright."

'To Find Fault with Ourselves'

Stethoscope on Specialism and Research in Medical Education

> We are gathered here today to find fault with ourselves in order to strengthen our education by correcting our weaknesses. . . .
>
> Modern specialization, fostering security in a tight little compartment, has reduced the scientist to a role without individuality. . . .
>
> The practicing physician has a magnificent opportunity and duty to observe patients and add to the fundamentals of our knowledge of disease. This is also truly "research." . . .
>
> Some students may see in medicine a highly lucrative career and yearn only for the diploma as a certificate of a gilt-edged credit rating. These are not likely to be really educated by any method and it is best that they be denied admission to medical training. . . .

Those statements are a sampling of the combined provocativeness-introspection-experience-learnedness atmosphere which surrounded 1,048 participants at last month's 55th Annual Congress on Medical Education and Licensure. No holds were barred as several score speakers and workshop conferees prominent in and related to medicine and education sailed into broad phases and intense impacts of specialism and research. The place and perspective of research and specialism in the education and practice of medicine formed the motif of this year's Congress.

The Congress, Feb. 7-10 in Chicago, was sponsored by the A. M. A. Council on Medical Education and Hospitals in cooperation with the Association of American Medical Colleges, the Federation of State Medical Boards of the United States, and the Advisory Board for Medical Specialties. A highlight of the meeting was a three-point stimulus, suggested by A. M. A. President Gunnar Gundersen, "to insure" that all practicing physicians regularly keep abreast of important developments in medicine. He recommended that:

—Medical license holders be required to regularly participate in acceptable postgraduate programs.

—Holders of medical licenses be required at intervals to demonstrate, through reexamination, their retention of important basic knowledge and competencies, and their awareness of significant advances in medicine.

—Reexamination and/or postgraduate education be required "for continuing membership in organized medicine, specialty and other medical organizations."

"I am not at all certain which of these methods is best," said Dr. Gundersen. "The first [reexamination] would produce the quickest results, but there is no assurance it is best. This is a matter for careful study . . . not in 1965 or 1975 or some later date. The public and profession must be assured now of the high standards and qualifications of physicians." Dr. Gundersen also brought out these points:

Medical men must work cooperatively with others or have others superimpose a way of medical life that may give medicine little voice.

There is a need for the extension of a uniform policy of endorsement or reciprocity of medical licenses.

Medical educators and others should explore the feasibility and desirability of requiring at least two years of approved hospital training after medical school ("one year is not adequate preparation") before being eligible for full licensure.

Following are excerpts from other presentations:

EDUCATION'S SCOPE AND SPAN—

The introduction of the longer hospital period of training plus the requirements of military service after graduation have intensified the challenge to reduce the long span of professional education. The most satisfactory solution may be not to interfere with the medical course per se, which is currently undergoing intensive revisions and improvements, but to strengthen and vitalize the period of secondary and college education.

—Willard C. Rappleye, M.D., President,
Josiah Macy Jr. Foundation

For a long time the vacuum represented by the high school will remain a heavy drag on medical education. For all practical purposes the three to four years in college only enable medical students to obtain knowledge which should have been obtained in a high school of good standing. . . . The medical student of today should be educated not only for the year 1959 but also for the four following decades, because he will probably still practice medicine in the year 2000. The knowledge of today will be ridiculous in 40 years.

—Isidore Snapper, M.D., Beth-El
Hospital, Brooklyn, N. Y.

If you are five years behind in your thinking now, you are more out of date than your fathers would have been if they were 25 to 50 years behind in their thinking. You have to run faster and faster to stand still. . . . We can stockpile medical supplies and equipment. We cannot stockpile doctors. That is why strong programs of medical education are so vitally necessary.

—John S. Patterson, Deputy Director,
Office of Civil and Defense Mobilization

LIMITS AND EXPANSE OF SPECIALISM—

One of the lasting tributes to the genius of the great classic figures in medical science is the ingenuity they displayed for inventing not only new techniques but often whole new concepts in fields quite outside their own. But the climate has changed. The solution (of a problem at hand) would seem now to be as simple as adding one more "specialist" and congratulating oneself that the approach is

This Matter of Resident Pay . . .

There were four workshop conferences in conjunction with the Annual Congress on Medical Education and Licensure last month and not one was scheduled to look into the economic problems of residents. Yet, these very problems popped up at three of the sessions, and were duly noted.

One summary report stated: "It was agreed that residents are underpaid and that some had to work out of hours for pay to support wife and family." Another noted: "There is no doubt that many who wish to continue residency training are unable to do so because of financial handicaps and are unable to borrow." And, according to a third workshop summation: "Young men and women in residencies should be looked upon as graduate students and their economic needs should be met from that point of view rather than from the point of view of their contributions to hospital service."

Discussions were not all in that vein, however. A participant on one panel, Columbia University Sociologist Patricia Kendall, told of her findings on medical student attitudes: "The quality of teaching was by far the most important consideration that led them to choose a particular hospital for their internship and residency. Salary ranked very low in their stated considerations."

Another workshop group agreed that whatever the source or amount of resident pay "it is perhaps forgotten that in one way or another the cost is ultimately passed on to the patient." When the question was raised whether high compensation would help or hurt, the conferees said they detected some feeling that "too high levels of payment might lead to undue prolongation of periods of resident training." A physician on that panel said, "In my day, as residents, we felt we were lucky to get what we got. Our babies were our own responsibility and not the community's. Residents should have enough to live but demands need not be met in toto."

Two other physicians felt that the problem was indeed serious but not being portrayed in proper perspective. They reported: "Although salary is not usually the major inducement for choosing a particular residency, lack of adequate funds often requires the resident to make compromises in his career plans. And these compromises frequently limit his potential development."

One of four workshop conferences in session during Annual Congress. This one discussed "The Specialty Board."

"modern" because it shows evidence of "multidisciplinary integration."

—S. Marsh Tenney, M.D., Dartmouth Medical School

Only by concentrated, competent, and enlightened attack at numerous limited areas as they open up to us as we continue investigation can we ever hope to begin to understand the whole. By this token one can confidently predict that true specialism in science will continue to survive and multiply.

—Paul M. Gross, Ph.D., Vice-President, Duke University

Specialism is in effect threatened by its own technological instrumentation. I cannot envision automation taking over the surgeon's work, but it may well take over that of the anesthetist.

—Iago Galdston, M.D., New York Academy of Medicine

Only when specialization is premature, or is disassociated out of context with the whole, does it have an adverse effect. This is as true of the mechanic who tightens one bolt on an assembly line as it is of the doctor who gazes into only one orifice of the body.

—Herman Pearse, M.D., University of Rochester School of Medicine and Dentistry

Now and again the medical profession will single out a general practitioner toward the close of an honorable career and give him public honors, but there is something sentimental and nostalgic about this gesture. It is as though there had been introduced the practice of honoring the knight of the year during the late middle ages after the invention of gunpowder and firearms. . . . The important consideration is the way in which the specialty is taught. All too often the approach is too restricted. It is too often directed toward producing the clever technician and not the educated expert. What I suggest is that the proper human use of a specialty should be approached as a function not simply of the physician as a good man but of the specialist as a good physician.

—Moody E. Prior, Ph.D., Dean, Northwestern University Graduate School

RESEARCH—MOTIVE AND PRACTICE—

Every student has his own set of motivations. Some may see in medicine a highly lucrative career. Some may be highly motivated by a desire for service. A third group might include those who marvel at the wonder of nature that is man and want, more than anything, to understand more and more about this creature—it undoubtedly will be one of them who will help unravel the mystery of cancer, help us stem the deterioration of aging, help reverse the trend in mental illness. Their satisfaction is not in direct service but in indirect service.

—Conrad A. Elvehjem, Ph.D., President, University of Wisconsin

Research has been described in many ways. I like a recent definition of Bernard Greenberg's, "a burning yearning for learning." If the first letter of the last word is omitted, one sees clearly the common motive for violation of the essence of research. Too often research studies become the legal tender of academic life.

—Nathan A. Womack, M.D., University of North Carolina School of Medicine

SOCIOECONOMICS—

Medical insurance has had a catastrophic effect on residency training in surgery. In most university-owned teaching hospitals and in most private hospitals, insurance has converted the clinic into private patients. . . . The straightforward approach is to have the residents licensed to practice, and approved for the care of insurance patients. If a fee is involved it is accredited to the surgical staff, who should act as trustees of such funds. Unless something is done the public will become the unsuspecting subjects of inadequately trained surgeons. We must find a way to retain the benefits both of medical insurance and of the residency system of training.

—Herman Pearse, M.D.

Although many of our future interns have only modest means and are at the same time burdened by financial obligations, they clearly prefer the hospitals which offer a poorly paid internship with a well-integrated teaching program, and shun the hospitals where there are higher emoluments but where they will be abused as scribblers of medical charts.

—Isidore Snapper, M.D.

The changing social character of the student is probably responsible in part for the change in the attractiveness which medicine holds for him. If we fail to attract into medicine an adequate number of topnotch students who can acquire and use the broader and deeper understanding of basic biology and behavioral sciences in the care of patients, our educational program will of necessity have to lower its goals to fit the students with which it is provided.

—John A. D. Cooper, M.D., Northwestern University Medical School

Selected full texts of presentations at the Congress will be published in future issues of THE JOURNAL.

The Council on Medical Education and Hospitals is headed by Dr. Leland S. McKittrick of Brookline, Mass. Other members are Drs. W. Clarke Wescoe of Kansas City, Kan.; John Z. Bowers of Madison, Wis.; James M. Faulkner of Cambridge, Mass.; Warde B. Allan of Baltimore; John W. Cline of San Francisco; Harlan English of Danville, Ill.; Charles T. Stone Sr. of Galveston, Texas; Guy A. Caldwell of New Orleans; and W. Andrew Bunten of Cheyenne, Wyo. The Council Secretary in Chicago is Dr. Walter S. Wiggins.

Education Via FM Radio

Neither Weather Nor Work Keeps These Doctors from Their Studies

Richard P. Pratt

The temperature hovered in the mid-twenties and there was snow on the ground when nearly 100 physicians of New York's Hudson River Valley met at noon to hear a postgraduate medical conference on the treatment of acute vascular catastrophes.

Drs. Samuel Powers, professor of experimental surgery, and G. Rhemi Denton. assistant professor of surgery, spoke for 20 minutes and answered questions in an informal atmosphere. A mild note of humor was injected when one participant asked Dr. Powers to identify the ingredients of a "cocktail" sometimes given intravenously in cases of pulmonary infarct.

The session might have been indistinguishable from hundreds of other postgraduate offerings had it not been for one factor: the hour-long program was conducted entirely via a two-way FM (frequency modulation) radio system operated by the Albany Medical College. The faculty spoke not from behind a lectern, but in front of a microphone. Members of the audience were not forced to travel great distances to attend; participants listened—and asked their questions—from comfortable meeting rooms in eight New York hospitals, and some even managed to eat lunch during the period. All were able to return to their duties at one o'clock.

By means of this system, eastern New York state physicians have been keeping abreast of medical progress through the most natural medium, their medical school.

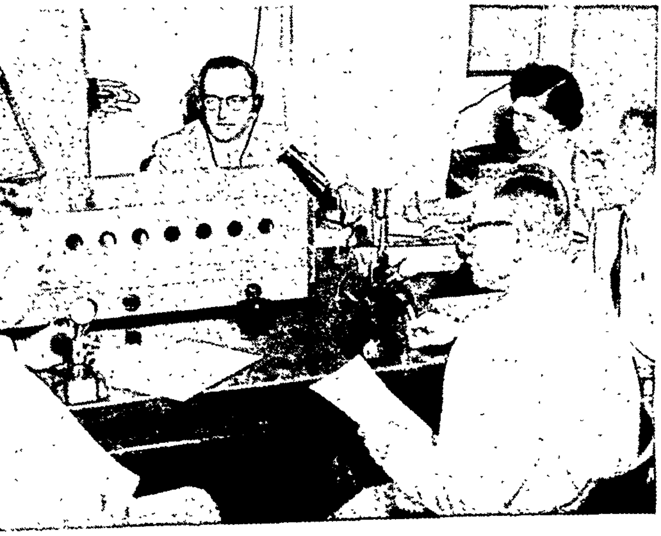
Postgraduate medical education by radio is the offspring of Dr. Frank M. Woolsey Jr., associate dean and director of postgraduate education at Albany. An amateur radio operator by avocation, Dr. Woolsey saw a chance to combine that interest with medicine when he came to Albany in 1954. The first network consisted of the medical school and three hospitals which happened to own amateur-operated transmitting and receiving equipment. When Dr. Woolsey switched his operations from short-wave to a noncommercial and relatively static-free FM frequency a little more than a year ago, his group had grown to include 21 hospitals with more than 75 amateur operators donating their time.

Outside Financial Aid

The work has been partly financed by grants from the Rockefeller Foundation which gave Albany $4,000 to begin its operations, and $90,000 for additional experimentation after its initial success. The current series is being sponsored in part by a grant-in-aid from E. R. Squibb & Sons. The basic plan is simple: Three times each week from November to May, two or three members of the Albany faculty go on the air with a 20-minute discussion of a subject chosen by a small committee of the medical college faculty. Ready and waiting at their own hospitals are physicians who have at their disposal transmitting and receiving equipment. As the faculty presentation ends, moderators transmit physicians' queries on specific points to the home station. Since there are usually eight hospitals participating in any given broadcast, they offer questions—two at a time—in rotation. Usually two complete circuits are made of the participating groups. Each hospital hears the questions asked by the other physicians and the answers broadcast by the faculty. Two similar broadcasts on the same topic are held during the same week to service the other hospitals on the network.

Dr. Woolsey's conferences have one big factor in their favor: they bring postgraduate education to the physician's doorstep, and thereby save him time, money, and effort. The fact that the doctor need give up nothing but his lunch hour probably accounts for some of their popularity.

But is it a satisfactory teaching method, this airwave classroom contact? Figures compiled for the first two years of operation show nearly 95% of the participating physicians rated the offerings



From Doctor to Doctor . .

Left, **faculty at Albany Medical College confer with staff of 23 hospitals via two-way FM radio. Clockwise from lower left are Harold C. Wiggers, Ph.D., dean; Albert Fredette, station manager; Miss Jeanne Roper, secretary; Dr. Frank M. Woolsey Jr., associate dean and director of postgraduate education; and Dr. William P. Nelson III, assistant dean and assistant director of postgraduate education.**

Wires and Wave Lengths

The use of two-way FM radio by the Albany Medical College is only one example of the profession's interest in electronic devices as aids in continuing medical education. Others include:

–Transatlantic telephone conferences between physicians in the U. S. and Great Britain at recent A. M. A. Annual and Clinical Meetings.

–Closed circuit color telecasts of surgical procedures and hospital rounds during the same meetings and in between, produced by pharmaceutical firms in cooperation with the A. M. A.

–A proposed open circuit series of telecasts on medical topics now being negotiated by a major broadcasting company and a pharmaceutical firm.

–A private circuit FM operation to carry news of medical advances and other postgraduate educational offerings to doctors' offices being planned now by another major network.

either "excellent" or "good" on opinion cards submitted after each session.

Other Schools Show Interest

Dr. Woolsey is a reluctant proselytizer for his new method. He says: "I do not want other schools to feel that they are being shoved in any way toward the possible development of two-way radio conference networks." But many of them have needed very little "shoving." Requests for information or visits by personnel have come from medical schools and hospitals in Pennsylvania, Kentucky, Massachusetts, California, and parts of Canada.

As in most experimental situations, the early days of Albany radio were not always smooth. On inquiry to the Federal Communications Commission in 1955, Dr. Woolsey was told that the amateur frequencies were the only ones available for the type of project he had in mind. Despite the inherent difficulties of trying to man any large number of transceivers with amateur operators on an inflexible schedule, this was accomplished and continued for two years. But by 1958, Dr. Woolsey, working with the FCC, developed a plan that utilized noncommercial FM frequencies and remote broadcast transmissions in a manner untried previously. He then proceeded to establish station WAMC with studios at the Albany Medical College and its antenna atop Mt. Greylock, the highest mountain in Western Massachusetts. The station has a 10,000 watt output and may be picked up by any FM receiver within 150 miles.

The cost of a radio system such as that used by Albany and its hospital network is not great. Dr. Woolsey estimates that a contribution of from $1,600 to $2,500 from each of 20 hospitals would be sufficient to pay for the purchase and installation of a system that would include a master transmitter at the medical school and remote pickup transceivers at each hospital.

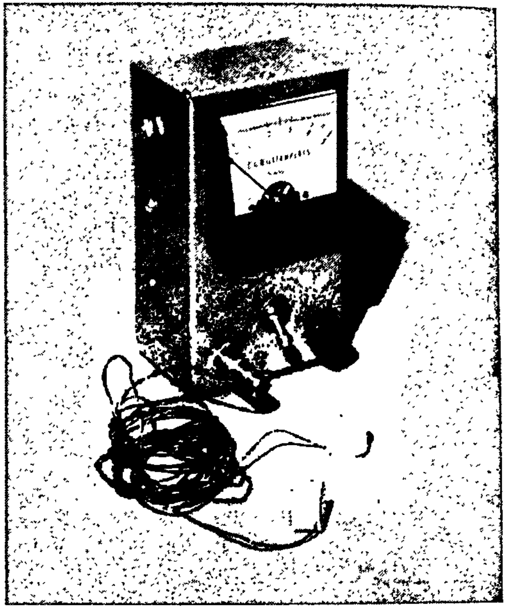
Postgraduate work by radio is not designed to replace intramural programs at the medical school, but rather to complement them. The subject matter of many of these courses, such as dermatology, precludes anything but personal attendance. Many others, however, lend themselves well to the radio technique supplemented if necessary by premailed mimeographed material.

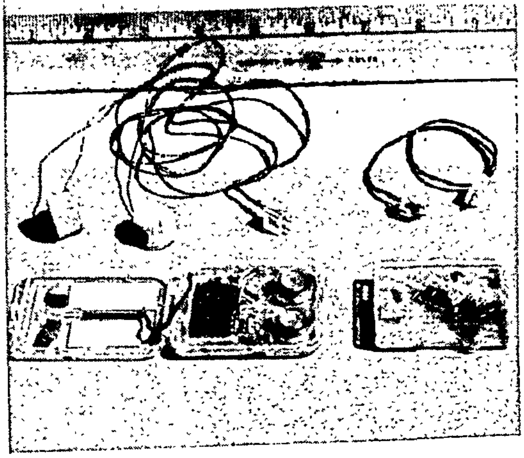
One of the initial qualms that accompanied the switch of Dr. Woolsey's system from shortwave to FM was the fact that using the FM band enlarged the potential audience from selected groups of doctors to any layman with an FM receiver. What would be the result if private citizens were exposed to lengthy discussions of diseases, conditions, symptoms, and treatment? Would such listening bring doubt and fear or would it send the listeners scurrying to their physicians with long lists of imaginary symptoms? No one knew for sure.

Experience with the Albany operation has shown no public inclination to take alarm from such broadcasts. Dr. Woolsey thinks this may be because laymen have found the discussions dull or unfathomable and therefore tedious. One New York physician has personal knowledge that at least one of his patients is a listener, however. The woman, who was recuperating, said she had listened to some of the programs and had been interested in the many questions asked by the participating physicians. She said: "It's nice to know that there are doctors who will admit they don't know everything."

. . Teacher to Practitioner

In hospital conference rooms, *right*, such as this one located at Vassar Brothers in Poughkeepsie, N. Y., physicians keep up with medical advances through the weekly radio series. During noon hour classroom time, they question faculty broadcasters by means of the transmitter in meeting room. Through network connection, they also hear other groups' questions.





Engineering and Medicine

How engineers work with physicians to attack specific health problems. *Upper left,* Dr. George V. LeRoy (in center) examines cytodiagnostic test apparatus for teaching laboratory technicians to recognize cancer cells. Punch card evaluates microscope slide. *Upper right,* electron stethoscope for quick visual and audible check. *Center left,* preliminary model of electronic calorimeter to measure changes in body heat. *Lower right above,* dime electrodes taped to chest, engineer demonstrates miniaturized heartbeat monitor to pathologist and telephone company president. *Bottom left,* close-up of same cumulative heartbeat recorder with amplifier. All devices are being developed by Illinois Bell Telephone Company engineers working during off hours in cooperation with University of Chicago medical researchers.

Togetherness in Heartbeat
Who Says Medicine and Engineering Don't Mix?

Two pathologists at the University of Chicago, Drs. Donald A. Rowley and Seymour Glagov, had a problem: How to keep accurate track of a person's heartbeats throughout a day or more without hampering his normal activities of work, play, and rest. This was no new question. Over the years many physicians have wondered about the relationship of pulse rates to circulatory diseases, smoking, body weight, occupational effort, maternal labor, sleep, athletics—to many aspects of persons in their environments.

Rowley and Glagov had one advantage over most of their colleagues, however. They could translate their problem into dramatic solution. And they did just that one day last month on the university campus when they displayed a 3-oz. device, comfortable and compact, that keeps a cumulative count of heartbeats. While the recorder (see photos on previous page) represents a significant medical advance in itself, even more important is the fact that it was produced in an atmosphere of liaison that signals growing cooperative efforts of physicians with practitioners of another discipline—engineering.

The relatively recent phenomenon of medicine at work with other arts and sciences has been noted previously as a powerful but still unsung force for progress in such fields as space exploration (Medicine at Work, THE JOURNAL, Jan. 31, 1959), basic research and medical education (Medicine at Work, THE JOURNAL, Dec. 21, 1957).

Those University of Chicago researchers, fortunately, had a catalyst in the person of William V. Kahler, a university trustee who also is president of the Illinois Bell Telephone Company. When medical faculty members posed some laboratory puzzlers, Kahler said: "Be specific. Tell me what you want, your immediate and most pressing needs."

Drs. Glagov and Rowley wanted a cumulative heartbeat recorder. Dr. George L. Wied of the department of obstetrics and gynecology wanted a cytodiagnostic test apparatus to help train exfoliative cytological technicians ("cancer detectives"). Dr. Klara J. Prec of the department of pediatrics wanted a tidal volume computer to help save newborn babies stricken with suffocating hyaline membrane disease. Mr. Donald Charleston of Argonne Cancer Research Hospital, which the university operates for the U. S. Atomic Energy Commission, wanted a special electronic circuit which could help pinpoint brain tumors.

The needs of these physicians are being fulfilled by nonphysicians—some 40 Illinois Bell Telephone Company engineers who belong to SAVE (Service Activities of Volunteer Engineers), a Chicago-area organization which is being groomed for national stature. Members welcomed the opportunity to exert individual initiative on their own time in garages, basements, and home workshops while serving medicine's goals to bring better health.

From Idea to Design to Product

Take the heartbeat recorder, for example. Engineers Leroy J. Ryan and Lou E. Harrington, given the medical problem, mapped out basic design and passed on the mechanics of construction to another telephone company employee, Watson B. McCreary, last September. McCreary, a watchmaker hobbyist for the past 15 years, picked up a $50 ladies wristwatch, removed the mainspring and hooked up the escapement mechanism of the modified timepiece to a pair of silver electrodes (dimes), some transistors, button-sized batteries, and a coiled magnet. In 90 days he created a gadget that ticks off the answers. The face of the "watch" does not tell time, of course. It is a form of adding machine. Modestly mass-produced, the precision device could sell to physicians for less than $200, according to Harrington.

Several weeks ago, Ryan linked it to a neon beeper in his living room and watched his five young children take turns "pasting on the dimes" so they could see and hear their own little heartbeats. Ryan himself kept a log:

"Saw the boss after work—113 beats per minute.

"Resting after kids to bed—86 bpm.

"Asleep—40 bpm.

"Fed baby before arising—61 bpm.

"Got up—65 bpm.

"Arrive work—102 bpm."

Harrington also kept a 24-hour log. One entry read: "Asked for raise—125 bpm."

"This invention is the equivalent of a $30,000 contribution to medical science," said Dr. Rowley. "But the patience, understanding, and willingness of these men to develop the instrument are invaluable. Dr. Glagov and myself hope they have enjoyed working in this cooperative project as much as we have."

Nobody is seeking a monopoly. All of the electronic circuits, as they become refined, are being made available to the medical profession. The research cost on all four projects to date totals only $400 for materials, with the university footing the bill. As far as Dr. Wied is concerned, such a cost is ridiculously low. Evaluating the cytodiagnostic test apparatus developed for him, he says: "The machine is priceless. It does not require me to stand behind each student to score each example. It gives me more time to devote to patients while

Discussion groups such as this at the Chicago conference hammered out recommendations on the expansion and improvement of homemaker services. Clockwise around the table are Miss Phyllis Osborn, Bureau of Public Assistance, Chicago; Miss Constance Hastings, Bureau of Public Assistance, New York; Mrs. Asher Yaguda, Newark; Dr. Marian R. Stanford, State Department of Health, Trenton, New Jersey; and Miss Margaret Gregg, State Department of Public Welfare, Austin, Texas.

still being able to train cytology technicians who are so badly needed."

"Medical Engineering"

The medical school as a whole, meanwhile, is sold on this kind of medical engineering—or engineering medicine, if you will—as a fitting key in research efforts. Dr. George V. LeRoy, professor of medicine and associate dean of the University of Chicago Division of Biological Sciences, says: "The present program of research cooperation with the members of SAVE is significant because it permits our clinical people to take advantage of a large store of information, the existence of which is either unknown to us, or to which we have limited access.

President Kahler of Illinois Bell is looking ahead, not only to more cooperative efforts of his fellow engineers with the medical researchers but to tapping a rich source of seasoned talent—the 195,000 active and retired telephone company workers who live in every region of the United States and Canada and who are ready to devote 20 or more years of individual know-how to supplement the community-serving activities of SAVE. They are called Telephone Pioneers, and Kahler is their international president. He says:

"This teamwork between dedicated and competent medical research doctors and telephone engineers is an outstanding example of public service. Their joint developments may be responsible for breakthroughs, which might otherwise have not been possible so soon, in the frontiers of biological science—and we know there will be more. Although we haven't come up with an electronic cure for the common cold—give us time—the advances to date demonstrate how two groups, with different professional backgrounds, can team up to solve problems for the common good."

Homemaker As One Prescription For Today's Troubled Family

HOMEMAKER, *n.* one whose occupation is household management.

The word denotes home operation, child rearing, and the creation of familial comfort. But Webster's definition could not have envisioned a different kind of homemaker—one emerging as a product of our modern times. The second definition includes all of the components of the first but with an important addition: she is available to take over when the family's usual "homemaker" is absent or incapacitated.

This second kind of homemaker was the one that interested some 400 persons who met in Chicago last month for the National Conference on Homemaker Services. Physicians, attorneys, social workers, insurance executives, labor representatives, nurses, industrial officials, and many others took part in the two-day session devoted to the exploration of ways to expand homemaker services.

A continuing interest in homemaker services has been expressed by the A. M. A. through committees of the Council on Medical Service. Dr. Philip S. Barba of Philadelphia, chairman of the Committee on Maternal and Child Care, acted as finance chairman for the Chicago conference. Section chairmen included Dr. Frederick Swartz of Lansing, Mich., chairman of the Committee on Aging, and Dr. Lemuel McGee, a member of the Council on Industrial Health.

A homemaker, under the definition used by this

One Family's Experience

A typical case for which the services of a homemaker were deemed a good solution to a family health problem is noted in an official report from Detroit:

"Mrs. M., the young mother of four children ranging in age from three to eight, was discharged from the hospital with a diagnosis of rheumatoid arthritis. Her children had been staying with relatives, and Mrs. M. was anxious to have them home with her. She could be up and around, but she was in pain, and her physician had ordered as much rest as possible. The Visiting Nurse Association helped with a plan in which a homemaker was assigned full time at first and then gradually reduced to one day a week. Mrs. M. did the meal planning, and the homemaker helped with the care of the children, cooking, light housework, and some ironing. As a result, the family was reunited and with rest Mrs. M. recovered. A total of 51 days of homemaker service were provided over a period of 19 weeks at a total cost of $612."

Persistence Succeeds in New Jersey

Much of the success in forming New Jersey's 13 homemaker services can be directly traced to the interest and persistence of two women—Mrs. Asher Yaguda, wife of a physician, and Mrs. Thomas F. Delaney, former executive director of the American Board of Pediatrics.

As members of the Essex County Service for the Chronically Ill in 1948, they conceived the idea of furnishing homemaker services to Essex County families who needed help. Their first attempts were to "sell" the idea to an agency which would implement it, but this they failed to do. Still undismayed, the two women then asked their own Service for the Chronically Ill to undertake the job despite the fact that the agency was specifically designed as a study group. With the backing of two physicians whom they had interested in the project, they got the agency's approval and set out to find some money to implement it. Their first donation—less than $300, most of which had to go for workmen's compensation and public liability insurance premiums—came from a woman's club in Newark, but it put them in operation.

An article in a Newark newspaper brought in 30 homemaker applicants, 10 of whom were accepted. These 10 were trained by experts loaned by the Red Cross, Public Service Company, and the Newark Health Department. The initial class was graduated in 1950, and got its first case soon after—a woman suffering from multiple sclerosis. Use of the service by the community was not immediate, however, and it took time to make the nature and value of the service known to physicians and welfare agencies in the county. Once the service became known, service requests boomed.

Medically oriented to the nth degree, Chr-Ill Service, as it is now known, requires physician approval for all referrals. The wisdom of the rule is indicated by the finding that 93% of all families served by homemakers in the U. S. during a "study week" in 1958 had members who were ill or disabled. Chr-Ill is sponsored by the Essex County Medical Society, and other New Jersey county societies and women's auxiliaries have been in the forefront of homemaker work in other areas.

All New Jersey services have medical advisory committees, and in at least one instance a physician was so impressed with the value of a homemaker on one of his cases that he paid for the service himself.

Success in Essex County turned out to be only the beginning. In 1953, the New Jersey legislature passed a prevention of chronic illness act which included a provision enabling the state health department to provide "housekeeping aid services." It also named a State Consultant Committee on Community Homemaker Services, and chose as its chairman an expert in the field—Mrs. Asher Yaguda.

group, is "a woman who is employed to help a family help itself rather than to provide domestic aid as it is generally understood." She is chosen, trained, paid, and supervised by an agency which assigns her to homes where help is needed, most often because of illness or incapacity. She is equipped to care for the needs of the children, perform routine household chores, provide meals, and do the marketing.

In days past, the help of mothers, sisters, and neighbors was often enlisted by families faced with difficulties, but the mobility of the modern family has frequently left it isolated from relatives and often with only a nodding acquaintance with neighbors. It is this social vacuum which the homemaker capably fills—to help keep family unity until crisis passes.

Beginnings and Adaptations

Although the first homemaker service was begun more than 30 years ago, only 150 of the nation's 3,100 counties have such a service available today, and in most of these the service is less than optimum. The Public Health Service reports 1,778 homemakers were employed in the U. S. in 1958 by 145 agencies. Three out of four (111) of the services are operated by voluntary agencies. Most of the remainder are programs of departments of public welfare.

Homemaker services were begun in different parts of the nation for different reasons, but all have a basic similarity:

—In New York City in 1933, the Homemaker Service of the Children's Aid Society was established as a joint experimental project with the Junior League. Its purpose was to come to the aid of distressed children by helping to care for them in their own homes in preference to boarding them out.

—Aid in family emergencies arising usually out of the illness or disability of the mother was offered by a homemaker service begun in 1940 by the Boston Provident Association. The work is now being continued by the Family Service Association.

—Homemaker service was begun in Cincinnati in 1930 when it was established with public funds as a WPA project. By the time public money was no longer available, the need for such a service was so obvious that it was taken over by the privately financed Family Service of Cincinnati and Hamilton County.

—New Jersey, where establishment and promotion of homemaker services has been widely endorsed by the state and county medical societies, has one of the best programs (see box). Indeed, its 11 autonomous homemaker services, with the aid of the state health department, have trained 575 homemakers, a figure which equals nearly one-third of the national total reported in a 1958 survey.

—In 1937, an attempt at providing homemaker service for rural areas was begun by the Colorado State Department of Public Welfare.

Criteria for Assignment

Homemaker services vary in the conditions under which they will assign workers to homes. Many concentrate on families where children will be directly affected; some are occupied with the problems of families faced with chronic illness; others attempt to serve any obvious need. The problem of payment by the recipient is met in many ways too. Usually those who are able to make their own payments do so directly to the agency. In other cases, they may make payments according to their ability based on a sliding fee scale. Homemaker services are sometimes purchased for recipients by welfare agencies.

Judging by the results of the Chicago conference, there is work ahead for those promoting homemaker services. Recommendations of the study groups which explored all phases of the future showed there is a need for:

—Broader understanding and support, especially from the groups which benefit indirectly such as industry and labor.

—The development of new methods for the establishment of homemaker services, particularly in rural areas.

—Study and evaluation of the existent variations in homemaker service programs.

—Provision for adequate money to meet the financial needs of the families served by homemakers.

—Clarification of policies of national voluntary agencies with regard to the role the local affiliate should take in participating in the organization of services.

One of the most valuable by-products of homemaker services is the opportunity they afford to mature women, many of them widows, to continue to play an important role in the community and to earn some money at the same time. Although the hourly wage of the average homemaker hovers near $1.25, the work apparently pays off in other ways. A visitor to one agency was introduced to an elderly lady identified as "one of our homemakers." She carried a book and, when the visitor asked what it was, she proudly displayed its title—"The Joy of Cooking."

A. M. A. Committee's Relative Value Study

The A. M. A. Committee on Medical Practices is now preparing its first publication to help state societies desiring to make relative value studies similar to those done in California, Kansas, and Iowa. The series of publications will include general information bulletins and survey manuals. These will be offered for inspection and comment at a series of regional meetings, the first of which will be held in San Francisco next month.

According to a Committee report to the House of Delegates last December, relative value studies may be used for several purposes but their chief value will be to enable health insurance and prepayment plans to set up benefit schedules that "bear a more constant relationship percentage-wise to the actual, usual or customary fees of physicians."

The Delegates agreed, called upon the constituent associations to consider the conduct of such studies, and directed that the Committee help them.

The stated purpose of a relative value study is to show—by some numerical designation other than money value—relationships between time, competence, effort, expense, and other factors required to perform one professional service as compared with those required for other professional services. Relative value studies are not fee schedules but may be the basis for developing realistic schedules of allowances.

Simply stated, the relative value study includes

Arguments Against Relative Value

What about the other side of the coin? Is there a case against relative value studies? Some physicians believe there is and have said so.

Perhaps their greatest objection is that, although the relative value principle makes only unit relationships between procedures, in practice this purpose could be subverted by those who might apply a set of dollar values to the scale, and then cry out against any deviation.

Another objection, voiced by at least one specialty group, is that proposed relative value studies do not adequately differentiate between procedures performed by a board-certified specialist as against the same procedures done by a physician without a specialty certification.

One objector bases his criticism on the fact that a given procedure with a set unit value on the schedule may in fact take much more time in one case than in another. Dr. Arnoldus Goudsmit of Youngstown, Ohio, writing in a national publication, uses that thesis to argue against relative values. As an alternative, he suggests that each physician determine his hourly rate and set fees according to the time given to the patient.

A Relative Value Sample in California

How might you use a relative value study in setting your own fee schedule? It can be easy, according to information published for the use of California physicians who wanted to do just that:

Once the physician receives his copy of the relative value scale, he has only to use the dollar value of some fundamental service in his practice—such as a follow-up office visit—and apply it as a basis for computing his normal fees for the other procedures listed in the scale. Such calculations need be made only once, and then kept for referral purposes.

But for those mathematically inclined, the California report explains it this way:

"If you normally charge $4 for follow-up office visits (Procedure Code No. 006 in the California study) which has a relative value of 35, how much should your fee be for a first home visit (003) which has a relative value of 70? Use this formula: $4 is to 35 as X is to 70. Multiply $4 by 70, which is $280; divide by 35 and your answer is $8—or the dollar value of the first home visit.

"You can establish your own conversion factor. Four dollars for a follow-up visit is approximately 11.42% of 35, its relative value. Take 11.42% of the relative value of each procedure, and you will have a fee schedule with correct values based on a $4 follow-up office call."

two elements:

—A comprehensive survey of the relationships between the usual charges made by members of the constituent association for professional services.

—A statistical evaluation resulting in the assignment of a unit value for the various procedures.

The California Medical Association's pioneering study was adopted in 1956 after three years of committee work. It was updated and republished in late 1957, and is currently being revised. It has been used by both Kansas and Iowa as a model for their own studies. The relative value study as adopted in California is subdivided into four parts and contains separate schedules for medical services, surgery, radiology, and pathology.

In urging constituent associations to undertake studies of their own, the House of Delegates suggested "using the nomenclature, descriptions and code numbers of the California study to avoid confusion." In its report to the House, the Committee stated:

"Unless studies of this type are made in the near future and adopted by the medical profession, medicine runs the risk of alienating public opinion and losing its bargaining position with other agencies engaged in financing the cost of medical care. If medicine does not undertake this activity, it may be done by others who are much less qualified."

Dr. Lester D. Bibler of Indianapolis is chairman of the House of Delegates Committee on Medical Practices. Other members are Drs. James P. Hammond of Bennington, Vt.; Elmer G. Shelley of North East, Pa.; J. S. DeTar of Milan, Mich.; and James M. Kolb of Clarksville, Ark. Mr. George W. Cooley of Chicago is Staff Secretary.

Accentuating the Additive

Today, in some rural communities, you still find those who salt their own meat. In using salt as a preservative, they are practicing an art, the origins of which are lost in antiquity. But they are also using an "additive" under modern definition, and food additives are very much a modern subject.

This month, an amendment to the federal Food, Drug, and Cosmetic Act went into effect. Its major provisions (which won't be totally effective for 30 months) will be to make the manufacturer of any food additive responsible for proving his product is harmless to human beings. In the past, a chemical used as a food additive had to be proved unsafe before it could be excluded from grocers' shelves by court action.

Under the new regulations, the manufacturer must make acute, subacute, and chronic oral toxicity tests using laboratory animals and submit the findings to the Food and Drug Administration which will regulate the quantities and usages.

Increased emphasis on the intermediary contract for hometown care of veterans with service-connected disabilities and efforts toward a return to the original principles of Medicare were discussed last month by the A. M. A. Committee on Federal Medical Services meeting in Chicago. Chairman of the group is Dr. Russell B. Roth (head of table) of Erie, Pa.

NAMING OF DRUGS ON PRESCRIPTION LABELS

UNLESS DISPENSED in original containers which have undetachable labels, most prescription labels bear only the name and address of the pharmacy, its prescription file number, the names of the patient and physician, and the latter's directions for use. The absence of any display of the name of the prescribed drug or drugs appears to be a matter of custom although intentional secrecy has been largely superseded by the use of English for writing prescriptions. Indeed, physicians frequently tell patients the name and nature of prescribed drugs unless there is a particular reason for withholding this information. Mutual confidence between physician and patient is likely to be enhanced by the plain designation of the principal ingredient(s) on the prescription label. The directions for administration are often too complex and varied to be encompassed on a small label; in some cases the warning to take only as directed may be the most useful inscription.

Identification of prescribed medication on prescription labels also may aid physicians other than the prescriber, as well as dentists, who may be consulted for the same or for a different ailment. Even the original prescriber may be unable to recall or find a record of the precise medication prescribed for a patient whom he has not examined recently. Moreover, the identification of a prescribed drug may be urgent in emergencies which involve a question of accidental poisoning, unintentional overdosage, or attempted suicide. Determination or confirmation of the exact identity of a previously prescribed drug in such cases may be hampered by the necessity for calling or contacting the dispensing pharmacy to obtain the information from the number of the prescription in its files. Such occasions, arising after closing hours, would involve even greater loss of time. There also may be other more or less urgent situations in which a clinic or private patient is obliged to consult or call an alternate physician for refill of a prescription, the identity of which can be determined only by contacting the office of the prescriber or the dispensing pharmacy. Indeed, on account of travel or changes of residence, patients may be put to extra expense because the identity and suitability of partly used prescriptions cannot be determined by another physician.

While display of the names of prescribed drugs on prescription labels can be advantageous, there are some patients for whom it may be unwise to reveal such information. These might include patients with mental disturbances, diseases known to have a fatal outcome, or any condition likely to be aggravated by a knowledge of its consequences, particularly if the name of the particular drug prescribed has a specific connection with the diagnosis. In such cases names which are therapeutically suggestive would be especially provocative. Another unfortunate aspect of prescription drug identification lies in the encouragement it may provide for sharing unused medication with another member of the household or a neighbor who has or is assumed to have the same illness. Because of wrong diagnosis, different stage of illness, or different dosage requirement, this could easily lead to serious consequences.

Although this is a delicate matter which should be left to the judgment of the physician in each individual case, it is suggested that with a somewhat larger section of the public than in former days the naming of drugs on prescription labels will work for good rather than for harm.

ANNUAL A. M. A. MEETING IN ATLANTIC CITY

Now is the time to make your hotel reservation for the annual A. M. A. meeting in Atlantic City which opens on June 8 and continues through June 12. The advance registration form and the hotel registration form appeared in the February 14 issue of THE JOURNAL, page 224.

Atlantic City has expanded its housing accommodations since the Association last met there. Nearly 5,000 new motel accommodations have been constructed within the city limits. Many of the motels are on or near the boardwalk. You are assured the widest selection of housing accommodations if you make your reservation now. A map showing the locations of the hotels and motels also appears on page 224 of the February 14 issue of THE JOURNAL.

ORGANIZATION SECTION

NEW COMMITTEE ON HYPNOSIS

At its meeting Feb. 6 and 7 the Board of Trustees voted to approve the establishment by the Council on Mental Health of a Committee on the Medical Use of Hypnosis. The Committee is composed of Drs. Harold Rosen, Baltimore, Chairman; Zigmond M. Lebensohn, Washington, D. C.; and Louis J. West, Oklahoma City. The date for the first meeting of this Committee has not, as yet, been set. The Committee will concern itself chiefly with the problem of implementing the suggestions and ideas expressed in the Council's report on the medical use of hypnosis, which was approved by the Board of Trustees and the House of Delegates of the American Medical Association and published in full in The Journal (Sept. 13, 1958, pages 186-189). The Board emphasized that the notice published in The Journal (Jan. 3, 1959, page 54) concerning the American Board of Medical Hypnosis in no way indicates that this "Board," which presumably has set itself up to serve as a certifying body for physicians using hypnosis, is connected with or approved by the American Medical Association or its Council on Mental Health. It is believed that two or three such groups have been set up in the United States. They seemingly allege in their announcements that they are functioning in collaboration with the Association or with the Council on Mental Health which definitely is not so. The general, and as yet unofficial, opinion of our Council's newly formed Committee on Hypnosis is that hypnosis itself has so far not advanced to the point where it can be considered to be a specialty apart from other medical specialties or apart from medicine in general. Dr. Harold Rosen, 1101 N. Calvert St., Baltimore 2, Chairman of the A. M. A. Committee, will be pleased to answer inquiries concerning problems of training in the use of hypnosis in practice from individual physicians and members of the Association.

PESTICIDES BOOKLET

A 64-page booklet, "Open Door to Plenty," is now available free of charge to A. M. A. members and others interested in learning how pesticides are used to protect food, property, and health. The easily read booklet is described as "an excellent summary of basic information" by the A. M. A. Committee on Pesticides, which makes a continuing study of precautions that should be followed for the safe handling and use of pesticides. Copies may be obtained by writing to the Committee at A. M. A. headquarters or to the publisher, the National Agricultural Chemicals Association, 1145 19th St. N. W., Washington 6, D. C.

FUNDS FOR MEDICAL SCHOOLS

A total of $4,133,839 was given to medical schools during the 55th Annual Congress on Medical Education and Licensure in Chicago, Feb. 9, by the National Fund for Medical Education and the American Medical Education Foundation. Dr. John McK. Mitchell, president of the Association of American Medical Colleges, accepted a check for $3,000,185 from Chase Mellen Jr., executive vice-president of the National Fund, and another $1,133,654 from Dr. George F. Lull, AMEF president. (See Medicine At Work in this issue for report on the Congress.)

CONFERENCE ON PHYSICIANS AND SCHOOLS

The seventh National Conference on Physicians and Schools will be held Oct. 13-15 at the Moraine-on-the-Lake Hotel, Highland Park, Ill. It is sponsored by the A. M. A.'s Bureau of Health Education. The conference is restricted to officially delegated representatives of state and territorial medical societies and health and education departments. More than 200 persons are expected to attend.

REVIEWS OF MEDICAL MOTION PICTURES AVAILABLE

The 10th annual publication of "Reviews of Medical Motion Pictures" is now available on request from the Film Library of the A. M. A. This publication is prepared by the Division of Communications, Department of Medical Motion Pictures and Television, and contains reprints of all reviews published in The Journal during 1958.

COUNCIL ON INDUSTRIAL HEALTH

PREVENTION AND CONTROL OF OCCUPATIONAL DERMATOSES

This is the last in a series of five reports prepared by the Committee on Occupational Dermatoses of the Council on Industrial Health, American Medical Association.

B. Dixon Holland, M.D., *Secretary.*

Occupational dermatoses cost this nation millions of dollars in lost time, lessened efficiency and production, and medical care and compensation each year. There are no figures which relate accurately the total cost of these diseases, but the money spent for medical care and compensation is admittedly excessive. These facts become more important when it is realized that occupational dermatoses are, in large measure, preventable.[1] Because of the continued prevalence of these diseases and the inconvenience and suffering which accompany them the Committee on Occupational Dermatoses has seen fit to review the measures which can be used to prevent and control occupational skin diseases.

The prime requisite in preventing occupational diseases in general and dermatoses in particular is cleanliness. Unless the workman, his clothing, his machine, and his working environment are kept clean there can be no control of skin diseases in industry. These essentials are attainable, for it is now generally accepted that appropriate engineering methods can control a noxious environment, and medical methods can do much to control the hygienic practices of the workmen.[2] For many years, large plants have been aware of the importance of providing a safe working place. The modern plant attains this by good construction, the installation of automatic equipment, and the use of closed process systems which protect the workman from harmful materials with which he must work. The basic chemicals can be transported to the plant in sealed cars, emptied into closed storage areas, and then piped into totally enclosed chemical reactor systems. Of course, this method of handling cannot be used in all plants because some processes do not lend themselves to closed systems or perhaps in certain plants the closed process may prove too expensive. With less cost, good ventilating systems to collect toxic materials can be used to control the spread of irritant vapors, fumes, mists, and dusts.[3] Competent guidance can be obtained from private consultants, universities, many of the state health departments, and some of t state labor departments who offer consultati services on industrial hygiene engineering pro lems.

Where good engineering devices are used to co trol the environment, occupational dermatoses a less prevalent. However, at the present time it estimated that less than one-third of the worki population has access to good environmental co trols within the plant. As a result, small plants wi poor environmental hygiene contribute heavily the sustained prevalence of occupational skin d ease.[3]

Responsibilities of Medical Department

Large plants rely heavily on their medical d partments to prevent occupational diseases. Co trols, including personal hygiene, are the respo sibility of the medical, industrial hygiene, nursin and safety personnel. Over the years, hygien practices have improved, and at this time a go medical department generally assumes the follo ing responsibilities directed at preventing occup tional skin diseases.

Education.—The first step in setting up a go educational program directed at preventing occ pational skin disease takes place when the medic industrial hygiene, safety, supervisory, and pr duction personnel develop a thorough understan ing of the existing hazards within the plant. This done by conducting a complete survey of all pla operations and observing the men at work so th the potential health hazards can be determine Once this appraisal of the hazards within the pla has been made, management, superintenden foremen, and old as well as new workmen shou be instructed about the hazards and the measu which must be taken by the men to avoid occup tional illness and injury. In plants where workm are not informed of the existing hazards, occup tional dermatoses are common. The physician w treats occupational dermatoses should visit t plants where the cases arise. Much can be learn about the causative factors which produce occ pational dermatitis, but, even more important, t physician can develop a practical attitude concer ing preventive measures.[4]

The members of the Committee on Occupational Dermatoses are Drs. Donald J. Birmingham (Chairman), Cincinnati; Leonard Weber, Chicago; Frank C. Combes, New York; A. Fletcher Hall, Santa Monica, Calif.; James W. Jordan, Buffalo; George Morris, Boston; and Ray O. Noojin, Birmingham, Ala.

Medical Preventive and Control Measures.—The intelligent use of the preplacement physical examination can do much to prevent occupational disease. Today, the preplacement physical examination is used to better define job assignments within the limits of a worker's mental and physical capacities. As with other systems, the skin is important in the preplacement physical examination, because thorough observation can lead to the detection of those abnormalities which are likely to be aggravated by the working environment. Practical application of this fact can be seen in a few examples. Young people with acne vulgaris have a predisposition for developing occupational acne from tars, pitches, certain chlorinated hydrocarbons, and, most of all, cutting fluids.[5] Individuals suffering from psoriasis or lichen planus can experience severe aggravation of their disease because of chemical or physical injuries to affected or unaffected parts of the skin.[5] The keloid formation tendency among certain members of the dark-skinned races provides another example. Rosacea becomes worse when workmen having this disease are exposed to heat or to the vapors of alcohol. Seborrheic dermatitis can be exacerbated by contact with oils and greases. The atopic skin, well known for its unpredictable behavior, can be adversely influenced by dusts, solvents, exposures to grease, and temperature and humidity changes.[6] These dermatological facts can be of infinite value to the alert examining physician in the preplacement examination and in the management of the employee at work.

At times, it is not possible to prevent completely the occurrence of occupational dermatoses. It then becomes highly important that the physician be able to control isolated cases or outbreaks of skin disease which are occurring within the plant. This cannot be done, however, unless the physician is able to recognize the cutaneous disease as being of occupational origin and then to identify the causative agent. When recognition of the disease and its cause can be done promptly, the attack of dermatitis will be minimized and the man can generally continue to work by using proper protective devices. It is utterly impossible to control dermatoses of contact origin if the cause has not been detected and the patient is permitted to undergo continued exposures.

Personal Cleanliness.—Personal cleanliness is invaluable in preventing occupational skin disease. Industrial ventilation systems and good housekeeping are important in maintaining a clean environment, but there is no substitute for washing the hands, wearing clean clothes, and keeping clean. The basic necessities for the maintenance of personal cleanliness are the washing facilities and the proper skin cleansing materials. They must be adequate in number for the men who will use them, well designed, maintained in continuous working order, and, of no small importance, they must be conveniently located. If a workman must walk long distances in order to wash he generally will do so infrequently.[7] The type of cleansing material to be used should be selected for the job whenever possible. The number of times workmen must wash during the work shift will depend on the nature of the material being handled, but most workmen generally wash at least three times a day, for example, during the morning, before lunch, and again at the close of the shift. If the work soil is heavy, the workmen may find it necessary to wash many times during the course of the day. Skin cleansing is highly dependent on the type of industrial hand cleansers used, because removal of irritants and sensitizers from the skin must be thorough to prevent prolonged contact which leads to dermatitis. However, the frequent or even the infrequent use of harsh or poor quality skin cleansers may cause dermatitis, especially in those workers with dry skin or among those who work with solvents, alkali, and other materials that cause dehydration and removal of lipid.[8] Industrial cleansers include a wide variety of soap and related compounds in the form of plain soap powders, abrasive powders, abrasive cakes, liquids, and the so-called waterless hand cleaners. There are several well-known, time-tested industrial cleansers made by reliable producers. Powdered conventional soaps are usually satisfactory for the removal of heavy soil from the skin. In some of these powdered cleansers or cake cleansers, finely ground sand, pumice, powdered wood chips, and ground corn cobs, among other abrasives, have been added to the soap to effect better removal of the soil. Occasionally, this type of abrasiveness may overcome any mildness which is present in the soap. Corn meal and wood flour are considered efficient and acceptable abrasive additives.

Many of the cleansing agents also contain wetting agents, water softeners, and chelating agents. These improve the detergency of the soap, but they can also increase the potential irritant properties of the products, particularly if their continued use causes an increase in the pH of the skin.

Sulfonated oil soaps and other acidic skin cleansers (pH range of 7 or less) are good for cleansing the skin when soilage is less severe and easily removed. Schwartz and others [9] have found liquid sulfonated oils (soapless soaps) to be excellent cleansers for the removal of cutting fluids and even more tenacious soils. A distinct advantage of the sulfonated oil is that it can be used with less irritation to the inflamed skin by workmen with mild dermatoses.

Within the past few years, germicides, notably hexachlorophene and, more recently, tetramethylthiuram disulfide, have been added to soaps to increase their antibacterial power. Several industrial cleansers contain hexachlorophene and these can be used to advantage by food handlers, meat packers, and by those who have other exposures where bacteria play a primary role in causing occupational dermatitis.

Lanolin is a common additive to many industrial soaps. There is some controversy as to whether or not its presence is necessary, but it is believed that lanolin does tend to buffer the lipid-removing and dehydrating actions of soaps on the skin.

A group of products which have attained a renewed popularity are the waterless hand cleansers. These preparations are usually semisolid cream or paste or liquid materials which cleanse the skin without requiring use of water. They exert their action on the skin either by their wetting agent content or by solvent action, or by a combination of solvents and alkalis. Most of the waterless hand cleansers remove oils, greases, grimes, and paints, with other heavy soilage from the skin, quite satisfactorily. This advantage provides a selective utility for removing certain soils which ordinary soaps fail to dislodge completely. A good waterless hand cleanser can replace effectively raw solvents so commonly used for hand cleaning purposes. They have a definite application in operations where machinists, mechanics, field crews, road gangs, and maintenance men must walk long distances to obtain washing facilities. Several of these products are considered acceptable for use and have been on the market for at least five years, but waterless cleansers do not constitute a replacement for soap and water in all jobs.[10]

A few years ago, Dr. Louis Schwartz,[7] in a publication entitled "The Prevention of Occupational Skin Diseases," written for the Association of American Soap and Glycerine Producers, Inc., suggested the following basic requirements in selecting industrial skin cleansers, which, if followed, will generally lead to the choice of a satisfactory one:

1. They should quickly and efficiently remove industrial soil.
2. They should not harmfully defat the skin by normal application.
3. They should not be unpleasant to use.
4. They should not abrade the skin.
5. They should not be strong skin sensitizers.
6. They should flow easily through dispensers.
7. They should not become insect infested under normal storage conditions.
8. They should not clog the plumbing.

The industrial physician, safety director, or the consulting dermatologist should be able to select an industrial cleanser which is not harmful to the normal skin and which at the same time will remo efficiently the soils encountered. This is not a dif cult task if the one selecting the cleanser und stands the basic essentials concerning the action soaps on the skin, and, in addition, has some miliarity with the well-known products availal for purchase.[11] Considerable information along tl line can be obtained by referring to the abo mentioned work by Schwartz.

Protective Clothing.—In some plant operatio the workman finds it impossible to keep his clo ing clean no matter how carefully he handles t materials with which he must work. Work clothi laden with irritant or allergenic chemicals can p duce dermatitis. Similarly, oil-saturated shi trousers, or shoes induce comedones, erythen and dryness of the skin, and eventually occu tional acne.

Present-day protective garments are both attr tive and useful. They can be made from rubb leather, cotton, or synthetic fibers. Some of the n fabrics will protect specifically against acids alkalis, others against extreme degrees of he cold, or moisture. In highly hazardous operatio it is common practice for plants to furnish workmen with protective clothing. When clothi is furnished by management, there is better cont over the wearing, laundering, and servicing of garments. In addition, this practice insures agai the hazard of laundering the family clothing w noxious chemicals contained in the work cloth In plants where a workman must furnish his o protective clothing, there is little or no control o the type of protection furnished and not inf quently the prevalence of dermatitis cannot lowered. Some operations require the wearing impervious gloves and/or sleeves; however, recommending these devices, knowledge of operation in which the sleeves or gloves are to worn is essential. For example, a protective slee or glove worn near moving machinery could be cause of a serious accident. We have found tl surgical stockinet sleeves and cotton gloves protect the hands, wrists, and forearms agai moderate dust exposures. These materials are expensive; they are not cumbersome; and, by is ing two or three pairs of gloves and sleeves perio cally, they can be changed as often as necessa

Aprons can be obtained in fabric or plastic n terials. They have special value in protecting body against cutting fluids. The apron shou cover most of the chest and extend below knees. If the apron is to be an effective protecti however, it must be cleansed daily.

Protective gloves can be made of leather, natu rubber, synthetic rubber, or plastic material. T seams should be smooth to avoid trauma wh wearing. When gloves are worn to protect the hands against irritant chemicals they should cover most of the forearm, and the cuff should fit under an impervious sleeve which fastens at the wrist. This prevents the entrance of chemicals into the glove cuff.

Rubber gloves are an essential protective device in certain exposures to chemicals. Before recommending them, however, the nature of the exposure should be ascertained, because natural latex rubber gloves will not protect adequately against oils or chlorinated hydrocarbons. For these exposures, synthetic rubber or neoprene-dipped gloves must be worn. On occasion, the wearing of rubber gloves may produce eczematous-like lesions of the hands in those individuals whose perspiration is excessive. To combat the latter problem, and to provide greater comfort for all workmen who must wear rubber gloves, it has become common practice to advocate individual cotton liners underneath the rubber gloves. These can be changed as often as necessary.

Where potent skin sensitizers are encountered and the incidence of dermatitis without protection is high, it may be necessary to institute a more formal "protective clothing program." Educational elements to stimulate motivation and understanding and specific and detailed instruction in the use of protective clothing are essential. In some instances, regular and frequent inspection of the hands and arms by the nurse or the supervisor has facilitated the early identification of dermatitis.

A word of caution concerning protective clothing is given to the plant physician as well as to the consultant who on occasion can be misled by the workman who claims that he always wears protective clothing, including gloves. A few moments spent in examining the gloves or other garments may save considerable time in making a diagnosis, since wearing of clothing or gloves impregnated with irritant or sensitizing chemicals makes it impossible to avoid cutaneous contact with these materials.

Barrier Creams.—Barrier creams, or protective ointments, are popular with workmen, but these materials do not provide the degree of protection afforded by properly designed and maintained protective clothing. Notwithstanding, there are instances in which these preparations can be used to great advantage. Such is particularly true in occupations where wearing a face shield would be too cumbersome, or where skilled workmen cannot wear rubber gloves because of interference with the sense of touch. Well-instructed workmen understand clearly that a barrier cream, to be effective, must be applied to the skin before beginning work, washed off before lunch, reapplied after lunch, and again removed at the close of the workday. If the areas to be protected become soiled in between these periods, it may be necessary to remove and reapply additional barrier agent. In those plants where the program of occupational health is poor or absent, the workmen, through lack of instruction, generally do not understand the need for this routine. As a result, they sometimes develop a false sense of security with respect to barrier creams. Indeed, it is not uncommon to find workmen treating their cases of dermatitis with the barrier agents designed to prevent the eruption. Basically there are three types of protective or barrier creams: 1. The simple vanishing cream, or the invisible glove type cream, which fills the pores to prevent the entrance of irritants. Because of the formula, soil is easily removed along with the barrier cream on washing after work. 2. The water-repellent type which permits the formation of a film of water-repellent substance such as lanolin, beeswax, petrolatum, or silicone on the skin to prevent contact with water-soluble irritants such as acids and alkalis.[12] 3. The oil-repellent and solvent-repellent type which depends on water-soluble gums such as acacia, tragacanth, methyl cellulose, or moss gel to repel oils and solvents.

At this time, there is no all-purpose barrier cream which protects against all materials handled at work. For this reason, considerable thought must be given to the type of barrier cream prescribed. It is a waste of money and time to have the workman or the patient use a water-repellent cream when he is also exposed to solvents or light oils.

Conclusions

The majority of occupational dermatoses can be prevented by maintaining a clean working environment, but where environmental control is poor the most essential factor is maintaining cleanliness of the skin and the clothing. Workmen must be taught the importance of cleanliness and furnished with the necessary facilities to keep clean. Where possible, protective clothing and barrier creams should be used to support personal cleanliness. If these basic rules are not recognized by management and followed by the workmen, occupational dermatitis is inevitable.

Failure by the attending physician to appreciate these basic necessities frequently leads to protracted cases of occupational dermatitis. The therapeutic approach in the management of these diseases can be appropriate and rewarding, but it will prove fruitless unless the physician recognizes fully the significance of the contact factor in the plant and directs his major effort toward preventing further contact.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

POSTGRADUATE COURSES FOR PHYSICIANS

Notice of the following postgraduate courses for physicians has come to the attention of the Council on Medical Education and Hospitals since the publication of its annual list in The Journal, Aug. 16, 1958, for the year beginning Sept. 1, 1958. Each year a greater proportion of postgraduate courses are planned sufficiently in advance to be included in the annual listing, which provides a central reference more likely to bring courses to the attention of potential physician enrollees than can supplementary notices. Considering that more than 90% of the courses that eventually come to the attention of the Council are now included in the annual listing, it is expected that it will be possible to include all of the courses for the year beginning Sept. 1, 1959, in the annual listing, without supplementary notices. However, bringing the following information that has come in to the Council office to the attention of the profession appears desirable at this time.

The Medical Division of the Oak Ridge Institute of Nuclear Studies will conduct the second week of a pre-clinical course in **radioisotope methodology** for physicians April 27-May 1, 1959. The first week of this course was presented in February. Participants should have a basic familiarity with the techniques of using radioisotopes in medicine. The course will be repeated beginning June 1. Another three-day course in **thyroid measurements** will begin on July 6, to be followed July 9-10 by its clinical applications. Each course utilizes lectures, laboratory work, demonstration, audiovisual aids, open question periods, with the enrollee performing procedures. The fee for each course is $25. Requests for application blanks and further information should be directed to Mr. William B. Jones, Medical Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn.

The Department of Postgraduate Medicine of the University of Michigan Medical Center, University Hospital, Room 1610, Ann Arbor, Mich., can arrange tutorial clinical instruction in the **clinical use of radioactive isotopes** to aid the physician to qualify for use of radioactive isotopes in practice. Training is offered to one to four physicians at a time, licensed to practice medicine, who are usually certified specialists in radiology, internal medicine, surgery, or clinical pathology. Training is given simultaneously to residents in the hospital in these fields. The tuition is $50 per week.

A **Pediatric Symposium** will be presented on March 26-28, 1959, at the Auditorium, Texas Children's Hospital, Houston. Subjects will include staphylococcic disease, the neonate, infectious diarrhea in infancy, bone dysplasias, and diagnostic problems. For further information, address Dr. Russell J. Blattner, Department of Pediatrics, Baylor University College of Medicine, Texas Medical Center, Houston.

March 27-29, a postgraduate course in **congenital heart disease** will be presented at Grady Memorial Hospital, Emory University School of Medicine, 69 Butler St., S. E., Atlanta 3, Ga., at a fee of $50. For further information, write to Postgraduate Education at the above address.

The Twelfth Annual **Cancer Symposium** will be held March 31-April 1 at the Indiana University School of Medicine, Indianapolis 7. It will be devoted to the recognition and definitive management of neoplasms of the nose, paranasal sinuses, pharynx, larynx, the salivary glands, and regional metastases from these sites. There is no fee.

A one-day course on the **treatment of heart disease** will be presented April 29 at the Indiana University School of Medicine, devoted to the recent advances in the medical treatment of the various phases of heart disease. The fee will be $10. The following day, April 30, there will be a brief course on the **treatment of hypertension** to present the recent advances in the medical treatment of various hypertensive states. The fee will be $10. For further information, address the Director of Postgraduate Medical Education, Indiana University School of Medicine, Indianapolis 7.

The American College of Chest Physicians, 112 E. Chestnut St., Chicago 11, will present the Twelfth Annual Postgraduate Course on **Diseases of the Chest** for physicians in general and part-time specialty practice, at the Sheraton Hotel in Philadelphia, March 30-April 3 at a fee of $75 for college members and $100 for nonmembers. The methods of education will include lectures, panel discussions, open question periods, and audiovisual aids.

A one-day nine-hour course on **common neurological disorders for the general practitioner** will be presented April 15, 1959, at the Statler Hotel, Los Angeles, by the American Academy of Neurology. Educational methods will include laboratory work, seminar, lecture, panel discussion, open question periods, and audiovisual aids. The fee will be $10.

A course entitled **Topics in Clinical Medicine** will be presented May 11-16 at the Johns Hopkins Hospital, Baltimore 5. This five-and-one-half-day course is designed for physicians primarily interested in internal medicine. Registration will be limited to 150 physicians, at a fee of $100 each. Further information should be obtained from Dr. Philip A. Tumulty, Chairman, Postgraduate Committee.

A three-day course in **neurology** will be presented May 14-16 at the University of Colorado Medical Center, 4200 E. Ninth Ave., Denver 20. Further information should be obtained from the office of Postgraduate Medical Education at the school. That school will also present a course in **ophthalmology** on July 6-9 at Aspen, Colo.

The Eighth Annual **Postgraduate Seminar for Pediatricians** will be held at St. Christopher's Hospital for Children, 2600 N. Lawrence St., Philadelphia 33, May 20-23. This four-day 25-hour course for full-time specialists will include as educational methods patient demonstration, live clinic, bedside rounds, clinical conference, seminar, lecture, panel discussion, open question periods, and audiovisual aids. The fee will be $75. Further information may be obtained from the Professor of Pediatrics, Temple University School of Medicine, 3400 N. Broad St., Philadelphia 40.

The **Fourth Annual Postgraduate Course in Fractures and Other Trauma** for full-time specialists will occur June 8-13 at Cornell University Medical College, 1300 York Ave., New York City 21. The six-day 44-hour course will include as educational methods, clinical conference, seminar, lecture, panel discussion, and question periods. The fee will be $150. For further information address Dr. Preston A. Wade at the Medical School.

During the week beginning June 15, 1959, the **Second Annual Refresher Course in Diagnostic Roentgenology** will be held at the Cincinnati General Hospital, Cincinnati 29. The course will present various aspects of diagnostic roentgenology with emphasis on fundamentals. Enrollment is limited to radiologists and radiology residents, at a tuition fee of $150. Further information may be obtained from Dr. Benjamin Felson, X-Ray Department of the Hospital.

From June 18 through Aug. 1, 1959, the University of Michigan School of Public Health, Ann Arbor, will present a course in **health statistics.** Further information may be obtained from the Director, Summer Program on Statistics in the Health Sciences, at the School of Public Health.

The principles and techniques of **tissue culture** will be presented for medical research workers July 6-31 at the University of Colorado Medical School, by the Tissue Culture Association. This 26-day course at a fee of $100 will include laboratory work, seminars, lectures, with the enrollee performing as well as observing the procedures. Further information may be obtained from Dr. Mary S. Parshley, Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York City 32.

MEDICAL NEWS

ARIZONA

Hospital Plans Neurological Wing.—A new four-story neurological wing costing more than one million dollars will be added to St. Joseph's Hospital, Phoenix, with construction starting in about a year. The addition is made possible by a gift from Charles A. Barrow and his family, of Litchfield Park, and his mother Mrs. Beatrice H. Barrow, of Franklin, Pa. Their donation of more than $500,000 is being matched with federal funds. The new wing will be known as the Barrow Neurological Institute, honoring the memory of the late William E. Barrow, father of Charles and husband of Beatrice Barrow. It will be devoted to diagnosis, treatment, research, and training in neurology and neurological surgery and will be headed by Dr. John R. Green, of Phoenix, chairman of neurology and neurological surgery at St. Joseph's. The Barrow Institute will have 50 beds at the outset plus surgery and clinical and research laboratories.

CALIFORNIA

Dr. Daniel Blain Named Director of Mental Health.—Dr. Daniel Blain, of Philadelphia, was named state director of mental hygiene, succeeding Dr. Marshall E. Porter, who will return to his former position as deputy director. A native of China and the son of missionary parents, Dr. Blain has been professor of clinical psychiatry at the University of Pennsylvania since 1958 and for 10 years before that was medical director of the American Psychiatric Association in Washington, D. C. The new mental hygiene chief is presently serving part-time as director of mental health work for the Western Inter-State Commission on Higher Education.

Society News.—At a meeting Jan. 20 of the Los Angeles Society of Allergy the following officers were elected for 1959: Dr. Ralph Bookman, president, Beverly Hills; Dr. Isadore Pitesky, vice-president, Long Beach; and Dr. Catherine G. Pearson, secretary-treasurer, Pasadena.——The officers for 1959 for the Metropolitan Dermatological Society of Los Angeles are: president, Dr. Eliot Wolk, Sherman Oaks; vice-president, Dr. Max Popper, Beverly Hills; and secretary-treasurer, Dr. Murray C. Zimmerman, 301 E. Hadley St., Whittier, Calif.

Plan New Research Center.—The Cedars of Lebanon Hospital announced plans for the construction of a new research center. The new facility will be a two-story and full basement building of steel and reinforced concrete. This expansion will enable the hospital to extend its research activity beyond the 100 scientific studies presently conducted there during the year, according to Dr. Leo G. Rigler, Cedars executive director. The chairman of the 11-million-dollar Cedars Medical Center Campaign, currently in progress, is Alfred Hart, hospital trustee and president of the City National Bank of Beverly Hills. Now under construction as another step in the Cedars Medical Center expansion program is the new Rehabilitation Center, totaling one million dollars and designed for treating arthritis, multiple sclerosis, heart disease, and crippling involvements.

CONNECTICUT

Fund to Honor Dr. Hamilton.—Dr. Alice Hamilton, of Hadlyme, a founder of the profession of occupational medicine, was honored on her 90th birthday Feb. 27 by the establishment of a fund bearing her name at the Harvard School of Public Health, Boston. Dr. Hamilton is assistant professor of industrial medicine, emerita, at Harvard. She served first the Harvard Medical School and then the School of Public Health from 1919 until her retirement in 1935. Dr. John C. Snyder, dean of the Harvard School of Public Health, said the Alice Hamilton Fund for Occupational Medicine was made possible by contributions from friends, admirers, former colleagues, and students of Dr. Hamilton. In 1910, when the State of Illinois started the first comprehensive survey of occupational disease, Dr. Hamilton became the survey's director. In 1919 she joined the faculty of medicine at Harvard as assistant professor of industrial medicine.

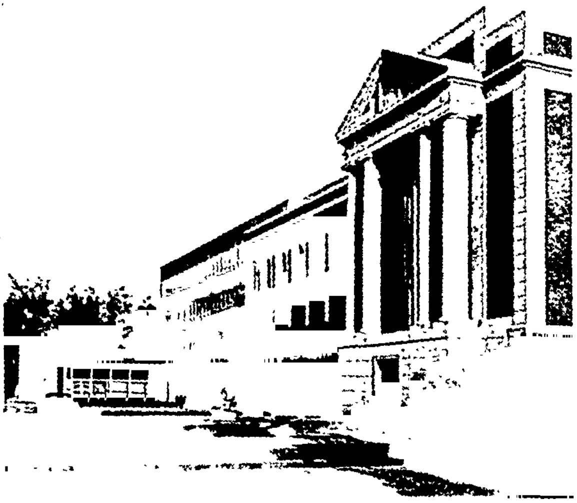
DISTRICT OF COLUMBIA

Dedicate Pre-Clinical Science Building.—The dedication exercises of the Pre-Clinical Medical Science Building at Howard University College of Medicine, Washington, were held Sept. 15. The dedication speaker was Mrs. Agnes E. Meyer, LL.D., who spoke on "A Plea for Scientific Humanism." The new building occupies the location of the original Medical School-Hospital built in 1869. On the ground floor is a lecture hall with a capacity of 250 persons, designed for use by outside groups for scientific meetings and other purposes. The

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

department of anatomy has its office and gross anatomy sections on this floor. The departments of pathology and physiology are on the second floor and those of biochemistry, microbiology, and pharmacology are on the third floor. The new department of preventive medicine and public health and the audio-visual aids section are on the South West Wing of the second floor. There are two amphitheater-type classrooms with a two-floor depth. The fourth and fifth floors are designed for research and animal care, and the sixth floor includes a unit for health care and study of insects. The fourth floor laboratories provide facilities for handling radioactive isotopes, high-speed centrifugation, thermal control, x-ray, and tissue culture. The fifth floor has facilities and operating suites for surgical procedures. Mordecai W. Johnson, LL.D., president of Howard University, presided at the ceremonies.



The new Pre-Clinical Medical Science Building at Howard University, Washington, D. C.

HAWAII

Hospital Celebrates Fiftieth Anniversary.—The Kauikeolani Children's Hospital of Honolulu is celebrating the 50th anniversary of its founding with scientific and social programs on April 19-22 at the hospital and at Princess Kaiulani Hotel in Waikiki. Dr. Tague C. Chisholm, of the University of Minnesota Medical School, Minneapolis, and Dr. J. Roswell Gallagher, director, *Adolescent Clinic*, Children's Hospital, Boston, will participate in the scientific program which also includes rounds at the hospital and at Hale Mohalu, Hansen's Disease Hospital. These meetings are open to the members of the medical profession. For information write Dr. Teruo Yoshina, Chief of Staff, Kauikeolani Children's Hospital, 226 N. Kuakini St., P. O. Box 3799, Honolulu 17, Hawaii.

ILLINOIS

Poison Control Centers.—Dr. Roland R. Cross, director, Illinois State Department of Public Health, on Feb. 16 announced that in January, 130 cases of accidental poisoning were reported to the department by local poison control centers in downstate Illinois. Thirty-one hospitals in 23 downstate communities cooperate in the state accidental poisoning report program. Each hospital provides emergency treatment and 24-hour telephone service to help physicians identify ingredients of various poisonous substances and to make treatment recommendations. All of the cases reported during January in downstate Illinois occurred in children under six years of age. Figures reported for the year 1958 indicated that 85% of all accidental poisoning occurs in children under 4 and that almost half of these cases involve a medicinal tablet of some form. Hospitals desiring to participate may address inquiries to Dr. Cross.

Chicago

Research Hospital Receives Merit Award.—Argonne Cancer Research Hospital received the U. S. Atomic Energy Commission's million-hour Award of Merit for safety Feb. 12. Dr. Leon O. Jacobson, professor of medicine at the University of Chicago and director of the hospital, accepted the award. Argonne Hospital is operated for the AEC by the University of Chicago as part of the University Clinics. Built in 1953, it reportedly was the first hospital especially designed and equipped to use all known radiation sources in studies of the treatment of cancer. The AEC Merit Award cites the hospital's freedom from accidents for 1,018,769 man hours from Nov. 2, 1955, to Sept. 30, 1958. It means that during this period no one working in the hospital lost any time from work because of injuries received on his job. Argonne Hospital employs 200 persons.

Lectures on Surgical History.—Thomas S. Jones, M.S., emeritus professor of medical and dental illustrations, University of Illinois, will present the *seventh in a series of lectures on the history of surgery* and related sciences at the International Surgeons Hall of Fame, 1524 Lake Shore Drive, March 24, 8 p. m., on "Evolution of Medical Illustrations." The lecture is open to physicians, medical personnel, and students, and to the public. There is no admission charge, but accommodations are limited to 300. For reservations, telephone Miss Virginia Cavanagh, MIchigan 2-3555, or write to Dr. Ross T. McIntire, executive director, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10. Dr. Edward L. Compere, chairman, department of orthopedic surgery, Northwestern University Medical School, will present the eighth lecture in the series April 14 on "The History of Surgery of Bones and Joints."

KANSAS

Professorship in Human Reproduction.—A research professorship in human reproduction at the University of Kansas School of Medicine was announced in January by Dean W. Clarke Wescoe. Named to the post is Dr. Thomas H. Clewe, who came to Kansas from the department of anatomy, Yale University, New Haven, Conn. Dr. Clewe's academic appointment with the University of Kansas is assistant professor, and he is associated with the departments of anatomy and obstetrics and gynecology. The professorship and appointment of Dr. Clewe was made possible through gifts to the Kansas University Endowment Association by friends of the university. A laboratory has been set up at the medical school where Dr. Clewe will conduct his study of the physiology of reproduction and application of tissue-culture techniques to the study of tubal function and fertilization.

KENTUCKY

Meeting on Public Health in Louisville.—The 11th annual Kentucky Public Health Association meeting is to be held at the Sheraton Hotel, Louisville, March 31-April 2, featuring addresses by Dr. Berwyn F. Mattison, executive director, American Public Health Association, and Dr. Gaithel L. Simpson, Greenville. An afternoon of "curbstone consultations" in the various disciplines of public health and another afternoon of special interest groups on school health, mental health, maternal and child health, public health tax, chronic diseases, and radiological health, are planned. April 2 will be devoted to section meetings. The health officers' section has Dr. Fred E. Tosh, assistant medical director, Communicable Disease Center, Kansas City Field Station, U. S. Public Health Service, to speak on "The Problem of Histoplasmosis," and Mr. Paul Vaal, director, St. Luke Hospital, Poison Control Center, Ft. Thomas, is scheduled to present a talk on "Poison Control Centers in Kentucky." The nurses' section has Dr. Walter D. Jones, medical director, District No. 4, Tuberculosis Hospital, Ashland, to speak on treatment trends in tuberculosis. At the laboratory section Dr. Malcolm L. Barnes, Louisville, and Morris Scherago, Ph.D., will discuss "The Relationship of the Division of Public Health Laboratories to the Private and Public Laboratory," and Milford Hatch, Ph.D., Atlanta, Ga., will speak on "Fluorescein-tagged Antibody Techniques in Rapid Diagnostic Procedures."

MASSACHUSETTS

Tufts Medical Alumni Dinner Meeting.—The annual Tufts Medical Alumni dinner meeting will be held on Wednesday evening, April 8, 1959, at the Somerset Hotel, Boston. The guest speaker will be Mr. Robert F. Kennedy, chief counsel, Senate Select Committee on Improper Activities in the Labor or Management Field. Other speakers will be President Nils Y. Wessell, Tufts University, and Dr. Joseph M. Hayman, dean of Tufts College Medical School. The 25-year class, M'34, will hold their 25-year reunion beginning April 6 and ending with the dinner meeting April 8. For information write Dr. Harry Blotner, Secretary, Tufts Medical Alumni Association, 136 Harrison Ave., Boston 11.

MICHIGAN

Lectureship Honors Dr. Darling.—An annual lectureship honoring Dr. Milton A. Darling, Detroit obstetrician and gynecologist, was announced Feb. 25 by Wayne State University College of Medicine. Dr. Darling was specifically cited for his contribution to medical education through his development of the resident training program in obstetrics and gynecology at Grace Hospital. He is president-elect of the Michigan State Medical Society, a past-president of the Wayne County Medical Society, and a diplomate of the American Board of Obstetrics and Gynecology.

Report of Rabies.—Four animal rabies cases were reported in Michigan during the first five weeks of 1959, and the Michigan Department of Health has urged dog and cat owners to have their animals vaccinated against rabies. The four rabies cases have been in widely scattered parts of the state. The first case was a pet dog owned by a farm family near West Branch. The dog died of rabies early in January after fighting with a wild skunk which presumably was rabid. A few days later, a young calf owned by a farmer north of Ann Arbor died of rabies. Source of the disease is not known in this case. Late in January, a dog owned by a family residing on the outskirts of Manistique died of rabies. A young boy was exposed to the disease by the dog and is receiving anti-rabies treatment. On Feb. 2, a pet cat owned by a family at Hart died of rabies. One member of the family was bitten by the cat nine days before it died and is receiving treatment. Sources of the rabies in the Manistique and Hart cases also are unknown. The calf rabies case was confirmed by tests made at the Pasteur Institute at the University of Michigan, Ann Arbor, and the other cases by tests at the Michigan Department of Health laboratories in Lansing. Last year Michigan had 38 animal cases and no human cases—there had not been a human case since 1948. The 38 cases in 1958 included 11 in the Upper Peninsula; 1958 was the first year since 1940 that rabies was reported north of the Straits.

MISSOURI

Annual Meeting in Kansas City.—The Missouri State Medical Association will hold its 101st annual session at the Muehlebach Hotel, Kansas City, April 5-8. Four panel discussions are planned and the following papers will be presented by out-of-state speakers:

Working Together for an Improved Missouri Mental Health Program, Dr. Addison M. Duval, Washington, D. C.
The Increasing Menace of Carcinoma of the Lung, Dr. Alton Ochsner, New Orleans.
Esophageal Hiatal Hernia, Dr. James H. Growdon, Little Rock, Ark.
Abnormal Uterine Bleeding, Dr. Roy G. Holly, Omaha.
Pancreatitis, Dr. Eric E. Wollaeger, Rochester, Minn.
Recent Advances in Roentgenology of the Biliary System, Dr. Lester W. Paul, Madison, Wis.
Present Day Concepts in the Treatment of Occlusive Cerebral Vascular Disease, Dr. Clark H. Millikan, Rochester, Minn.

Motion pictures, instruction courses, and exhibits are planned, and the annual banquet will be held April 7, 7:30 p.m., with Rev. Carl S. Winters, Oak Park, Ill., as speaker. Dr. Ferdinand C. Helwig, of Kansas City, will moderate a clinical pathologic conference the afternoon of April 6.

NEVADA

Cancer Seminar in Reno.—The American Cancer Society, Nevada Division, Inc., will present its annual Cancer Seminar March 25-26 at the Riverside Hotel, Reno. Two medical motion picture sessions on "Head and Neck Cancer, Tumors of Bone," and on "Moles and Melanomas, Tumors of Childhood" are planned. Four panel discussions have been arranged, and the following speakers and panelists are scheduled:

Drs. Weldon Bullock and Maurice Galante, Los Angeles; John W. Cline and Glenn Sheline, San Francisco; Edward C. Hammond, Ph.D. director, statistical research, American Cancer Society, Inc., John F. W. King, and Carnelius P. Rhoads, New York City; Peter A. Linstrom and Max W. Wintrobe, Salt Lake City; Kenneth C. Sawyer, Denver; and Michael B. Shimkin, Bethesda, Md.

The Seminar is certified for category 1 credit by the American Academy of General Practice. For information write Dr. Fred M. Anderson, 275 Hill St., Reno, Nev., Chairman, Seminar Committee.

NEW YORK

New York City

Dr. Lillehei to Lecture.—The third Bernard Sutro Oppenheimer Lecture will be given in Hosack Hall of The New York Academy of Medicine, 2 E. 103 St., April 2, 8:30 p. m. The lecturer will be Dr. C. Walton Lillehei, professor of surgery, University of Minnesota Medical School, Minneapolis. Dr. Lillehei's subject will be "Open Heart Surgery for Acquired and Congenital Heart Disease."

Dr. Kleiner Receives Award.—Israel S. Kleiner, Ph.D., director, department of biochemistry, New York Medical College, Flower and Fifth Avenue Hospitals, was awarded the third annual Van Slyke award of the New York Section, American Association of Clinical Chemists "in recognition of his pioneering contributions as a research investigator and as an educator." Dr. Kleiner lectured on "Hypoglycemic Agents—Past and Present."

Personal.—Dr. John J. Untereker, clinical instructor in physical medicine and rehabilitation at New York University-Bellevue Medical Center, was named director of the medical service at the Institute for the Crippled and Disabled, rehabilitation center at 23rd Street and First Avenue.—Dr. Nadene Coyne was appointed coordinator of training for physicians in the department of physical medicine and rehabilitation of New York University-Bellevue Medical Center and director of the Respirator Center at Goldwater Memorial Hospital.

Expand Rehabilitation Program.—The Institute for the Crippled and Disabled announced a major expansion of its education and training services for students and professional people pursuing careers in the rehabilitation of handicapped persons. To head its expanded program, the institute has named Isabel Pick Robinault, Ph.D., as director of professional education and training. At the College of Physicians and Surgeons, Columbia University, she is supervisor of postgraduate cerebral palsy courses and an instructor in occupational therapy. According to Dr. Robinault, the expanded program will offer opportunities in professional rehabilitation specialties to persons engaged in undergraduate as well as graduate study. Technical training in nonprofessional subjects will be provided. Among the joint rehabilitation teaching activities of New York University and the Institute for the Crippled and Disabled is vocational rehabilitation counselor training for graduate students. Teaching activities to be continued include courses of 10 months duration for makers and fitters of artificial limbs and braces, clinical affiliations for occupational and physical therapy undergraduates and for graduate nurses, psychologists, and rehabilitation counselors, a three-week course on the teamwork concepts of rehabilitation center operation, and six-week training programs in the conduct of vocational evaluation programs for the disabled. The faculties will be drawn from the staff of the institute and the faculty of N. Y. U. Wherever feasible, a course will be offered in collaboration with New York University and other participating institutions and college credits will be given.

OKLAHOMA

New Low in Maternal Deaths.—A new low of 3.7 maternal deaths per 10,000 live births, the lowest figure ever recorded in Oklahoma, is contained in a recent report by the division of vital statistics at the Oklahoma State Department of Health. Sepsis, toxemia, and hemorrhage are the major causes of maternal mortality now as they were 30 years ago, or even 10 years ago, according to Dr. John W. Shackleford, director of the division of maternal and child health.

OREGON

Annual Alumni Meeting.—The 44th annual meeting of the University of Oregon Medical School Alumni Association will be held April 8-10 in the school's library auditorium, Portland, according to Dr. John F. Larsell, president of the association. Registration will be 9-10 a. m. on the opening day. The group's scientific session will be presented in conjunction with the Sommer Memorial Lectures. Category 2 postgraduate credit will be allowed for members of the American Academy of General Practice attending the meeting. Evening social events will include fraternity reunions on April 7; the invitational Sommer Memorial Lecture banquet, April 8; the Alumni Association banquet, April 9 at Piluso's restaurant; and class reunions, April 10. Classes planning reunions include '34, '39, '49, and '54. The alumni will elect new officers and hear committee reports at the annual business meeting scheduled for the morning of April 9.

PENNSYLVANIA

Program for Training of Geneticists.—The department of biostatistics in the University of Pittsburgh Graduate School of Public Health will start training human geneticists next September. The purpose of this program will be to train research scientists who will study hereditary aspects of various diseases, particularly those relating to public health problems. Ching Chun Li, Ph.D., associate professor of biostatistics, will direct the new program. Dr. Li, who was head of the department of agronomy at National Peking (China) University, has been on the faculty of The Pitt Graduate School of Public Health since 1951. He has specialized in population genetics and is currently president-elect of the Society of Human Genetics. The program has been designed for advanced students who are trained in biology and have received at least a master's degree. The course of study will be tailored to the background and research interest of each student.

TEXAS

Annual Clinical Conference in Dallas.—The 28th annual spring clinical conference of the Dallas Southern Clinical Society will be held March 23-25 at the Statler Hilton Hotel, Dallas. Postgraduate lectures, round-table luncheons, panel discussions, and exhibits are planned. The following are listed as guest speakers:

Drs. Leo H. Bartemeier, Baltimore; Elmer Belt, Howard P. House, and J. Vernon Luck, Los Angeles; Edward P. Cawley, Charlottesville, Va.; Robert J. Coffey and Frank D. Costenbader, Washington, D. C.; Jerome W. Conn, Ann Arbor, Mich.; Charles Eckert, Albany, N. Y.; Philip J
Hodes, Irving H. Leopold, and William A. Sodeman, Phila
delphia; Charles A. Janeway and Frank D. Lathrop, Bos
ton; John W. Kirklin, Rochester, Minn.; Frank R. Lock
Winston-Salem, N. C.; Samuel B. Nadler, New Orleans
and Ernest Winslow, San Francisco

For information write the Dallas Southern Clin
ical Society, 433 Medical Arts Building, Dallas
Texas.

VERMONT

General Practice Meeting in Burlington.—A regul
meeting of the Vermont Chapter, American Aca
emy of General Practice, will be held March 26
the DeGoesbriand Memorial Hospital Auditoriu
beginning at 9:30 a.m. Dr. John C. Twitchell, Bu
lington, has arranged the following papers by Bu
lington participants:

New Approaches to Speech and Hearing Rehabilitation, I
troduction: Dr. Robert P. Smith.
Management of Hearing Loss; Medical-Surgical Aspec
Dr. Rufus C. Morrow.
Management of Speech Disturbances, (1) Neurological
pects: Dr. Herbert L. Martin; (2) Rehabilitation Aspec
Frank J. Falck, Ph.D.
Treatment of Coronary Insufficiency, 'Dr. Ellsworth L. Ar
don.
Modern Concepts in Therapy of Tuberculosis, Dr. Sinclair Allen.
Oral Treatment of Diabetes, Dr. George W. Welsh, III.
The Neurological Examination, Dr. George A. Schumach

VIRGINIA

Annual Lecture.—The Alpha Mu chapter of the P
Delta Epsilon Fraternity will hold its annual le
tureship series March 21 at 10:30 a. m. in the B
Johnston Auditorium of the Medical College
Virginia, Richmond. The guest speaker will be I
Cushman D. Haagensen, professor of surgery, C
lumbia University College of Physicians and S
geons, New York City. His subject is "Current Th
apy of Carcinoma of the Breast."

GENERAL

Glaucoma Identification Card.—A glaucoma iden
fication card for nationwide distribution was
nounced by The National Medical Foundation
Eye Care. The card, similar in purpose to
diabetes identification card, will alert examini
physicians that the patient has glaucoma and
using drugs. The names of the patient and of
ophthalmologist who prescribed the drugs appe
on the card, together with the prescription. T
glaucoma card also carries the spectacle prescr
tion of the patient. The cards were printed as
public service by Abbott Laboratories, and are
ing initially distributed to physicians by the labo
tories. Packets of the cards may be obtained
writing to the foundation office, 250 W. 57th
New York 19, or directly to Professional Servic
Abbott Laboratories, North Chicago, Ill. Educati
of the general public to the threat of glaucoma a

other eye diseases, with emphasis on the importance of regular medical eye care, is a basic purpose of The National Medical Foundation for Eye Care.

National Meeting of Chemists in Boston.—The 135th national meeting of the American Chemical Society will be held in Boston April 5-10. Chemists and chemical engineers from the United States and foreign countries will hold technical sessions in 10 of Boston's major hotels and auditoriums throughout the week, with the society's Northeastern Section as host. Prof. John C. Bailar Jr., of the University of Illinois, president of the society, will preside at a general assembly in John Hancock Hall April 6. Nobel Prize-winning chemist, Vincent du Vigneaud, head, department of biochemistry, Cornell Medical College, New York City; Prof. Robert B. Woodward, of Harvard, Boston; and Lewis H. Sarett, Ph.D., of Merck, Sharpe & Dohme Research Laboratories, Rahway, N. J., will attend. Progress in cancer research, chemical investigation in the fields of vitamins, proteins, and hormones and the development of a new class of antidepressant compounds will be discussed in sessions of the divisions of medicinal and biological chemistry. A report also will be made on recent research on the physiological effects of tobacco smoke. The American Chemical Society has more than 86,000 members and has 155 local sections serving 48 states, the District of Columbia, Puerto Rico, and Hawaii.

Select Orthopedic Surgeons as Exchange Fellows. Four American orthopedic surgeons selected as exchange fellows for a 7-week visit to England this spring are Dr. James S. Miles, University of Colorado Medical Center; Dr. Sherman S. Coleman, of the University of Utah School of Medicine; Dr. John P. Adams, Washington, D. C.; and Dr. Andrew H. Crenshaw, of Memphis, Tenn. They were advised of their selection by the American Orthopedic Association, which designates the visiting group every other year. The British Orthopedic Association makes the selections in the even years, and sent five physicians to the U. S. in 1958. The four surgeons will sail on the Queen Mary in April. During the stay in England the group will visit orthopedic centers and hospitals, will attend scientific meetings and conferences, and will be guests at social functions. Their expenses will be paid by the American Orthopedic Association. The U. S. quartet will have an audience with Queen Elizabeth, and will attend the annual meeting of the British association in May. They will return to the United States on the liner Queen Elizabeth in time for the meeting of the American Orthopedic Association at Lake Placid, N. Y., June 16-18. Physicians selected for participation in the exchange fellow program are under 40 years of age and are chosen for their "outstanding records and their professional interest in either private or academic medicine."

Award for Research in Norway.—The American-Scandinavian Foundation, which each year offers a number of awards for study in Scandinavia as part of its program to increase understanding between the United States and the Scandinavian countries, has announced the availability of one Clifford N. Carver Fellowship of $900 in Norwegian currency for medical research in Norway. Applicants must be American Citizens who have completed their college education. Ordinarily they should be under 40 years of age. No knowledge of Norwegian is required. Applicants will be judged on their plan of study and their ability to carry it out as indicated in the completed application. It is important that the plan of study be fully explained: it should be stated where the work will be done, the reasons for wishing to undertake or continue studies in the particular field, and the long-range professional objectives. The grants may be used in any way the grantee sees fit to aid him in his study. Normally they are paid in four installments. It is expected that the award winner will spend an academic year abroad. Applicants should plan to begin their study not later than Jan. 1. While an applicant may also apply for grants through other organizations, winners of ASF awards should not accept any other award without first consulting the foundation. Applications close April 1. For information and application, write the American-Scandinavian Foundation, 127 E. 73d St., New York 21.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing application is June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Apr. 15-17. *Reciprocity and Endorsement.* Phoenix, April 18. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

Delaware: *Examination.* Dover, July 14-16. *Endorsement.* Dover, July 23. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

Florida:* *Examination.* Miami Beach, June 21-23. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June 10-11. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Idaho: *Examination and Endorsement.* Boise, July 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination.* Chicago, April 6-9. *Reciprocity.* Chicago, April 10. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 17-19. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Iowa City, June 15-17. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

Kansas:* *Examination and Endorsement.* Kansas City, June. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, June 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maine: *Examination and Reciprocity.* Portland, March 10-12. Sec., Dr. Stephen A. Cobb, Sanford.

Maryland: *Examination.* Baltimore, June 23-26. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Ann Arbor and Detroit, June 8-10. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

Minneapolis:* *Examination.* Minneapolis, April 21-23. *Reciprocity.* Minneapolis, April 23. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Examination and Reciprocity.* Jackson, June 22-24. Sec., Dr. A. L. Gray, Old Capitol, Jackson 13.

Missouri: *Reciprocity.* Kansas City, April 6. *Examination.* St. Louis, May 29-30. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 15-17. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, March 3. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Jersey: *Examination.* Trenton, June 16-19. Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton 8.

New Mexico:* *Examination and Reciprocity.* Sante Fe, May 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* New York, Rochester, Syracuse, Buffalo and Albany, June 23-26. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Examination.* June 15-18. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, July 8-11. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Endorsement.* Columbus, April 7. *Examination.* Columbus, June 18-20. Sec., Dr. H. M. Platter, 21 West Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Written.* Portland, Apr. 17-19. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination and Endorsement.* Philadelphia and Pittsburgh, July 1-3. Sec., Mrs. Margaret G. Steiner, Box 911 Harrisburg.

Rhode Island:* *Endorsement.* Providence, March 26. *Examination.* Providence, April 2-3. Administrator of Professional Education, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity.* Columbia, May 12; *Examination.* Columbia, June 23-24. Sec., Dr. H. E. Jervey, Jr., 1829 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, March 25-26. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas:* *Examination and Reciprocity.* Fort Worth, June 22-24. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination and Reciprocity.* Salt Lake City, July 810, Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination.* Richmond, June 18-20. *Endorsement.* Richmond, June 17. Address: Board of Medical Examiners, 631 First St., S. W., Roanoke.

Washington:* *Examination.* Seattle, July 13-15. Administrator, Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Reciprocity and Endorsement.* Charleston, April 13. *Examination.* Charleston, June. Sec., Dr. Newman H. Syer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:* *Written.* Milwaukee, July 14-16. *Reciprocity.* Madison, April 17 and Milwaukee, July 15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, June 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, March 17. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

Colorado: *Examination.* Denver, May 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, June 6. Exec. Asst. Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, May 18-19. Address: Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N. W., Washington.

Florida: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, April 14. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Examination.* Kansas City, June 2-3. Sec., Dr. L. C. Heckert, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, May 8-9. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, April 7-8. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, May 5-6. Director, Mr. R. K. Kirkman, Bureau of Examining Boards, 1009 State Capitol Bldg., Lincoln.

New Mexico: *Examination.* Santa Fe, April 19. Sec., Mrs. Marguerite Cantrell, P. O. Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, June 5-6. Sec., Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Tennessee: *Examination.* Memphis, Mar. 25-26. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* Austin, Galveston, Houston, Apr. 17-18. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, July 8-9. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

Wisconsin: *Examination.* Madison, April 4. Final date for filing application is March 27. Milwaukee, June 6. Final date for final application is May 29. Sec., Mr. W. H. Barber, 621 Ransom St., Ripon.

*Basic Science Certificate required.

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

Neuropsychiatric Meeting.—The Ninth Annual Institute in Psychiatry and Neurology, sponsored by the VA Hospital, Lyons, N. J., and the New Jersey Neuropsychiatric Association, will be held Wednesday, April 1, at the VA Hospital, Lyons, N. J. The registration fee is $1. Military personnel and full-time veterans administration personnel may register without charge. The meeting will be held in building 5 and will start at 10 a. m. The program for the morning session will be as follows:

Relation of Epinephrine and Norepinephrine to Psychophysiologic Disease by William M. Manger, M.D., and Eric B. Schwarz, M.D.

Research in Social Psychiatry: Goals and Guidelines by Leo Srole, Ph.D.

Ego Breakdown in Schizophrenia and Its Implication for Casework Treatment by Esther S. Marcus, M.S.

Treatment of Hemiplegia by John Untereker, M.D.

The program for the afternoon session under the chairmanship of Ralph E. Snyder, M.D., will be:

Abnormality of Cerebral Transmission—A Neurophysiological Approach to Cerebral Disturbance by Amadeo Marrazzi, M.D.

The Current Status of Tranquilizers by Frank Ayd Jr., M.D.

Depressions—Recognition and Treatment by Leo Alexander, M.D.

The after-dinner speaker, Allan B. Monro, M.D., superintendent, Long Grove Hospital, Epsom Surrey, England, has for his subject "Comparative Aspects of British and American Psychiatry."

Dr. Barnwell Honored.—Dr. John B. Barnwell of the Veterans Administration was selected as one of the 10 top career men in the federal government for 1958-1959 by the National Civil Service League. The honor carries with it one of the league's annual Career Service awards. Dr. Barnwell, who heads medical research and education for the VA in Washington, D. C., was cited for his part in organization of the VA-Armed Forces cooperative study of chemotherapy of tuberculosis.

PUBLIC HEALTH SERVICE

Manual on Staphylococcic Diseases.—The Communicable Disease Center, Atlanta, Ga., has developed a 289-page training reference entitled, "Selected Materials on the Environmental Aspects of Staphylococcal Diseases." This volume, compiled by the Environmental Health Training Section, consists of 30 reprints together with appendices of additional readings, available training aids, outline of the hospital environment, and sources of further assistance. The selected articles contain information on hospital design; water and liquid waste disposal; solid waste storage, collection, and disposal; air hygiene; laundry and linen service; housekeeping; disinfection and sterilization; and the hospital environment in general. Copies of the manual are available from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., at a cost of $1.50 per copy.

CIVIL SERVICE COMMISSION

Openings for Physicians.—About 200 medical officers will be needed by the federal government this year for professional assignment in all of the specialties. Experience requirements range from doctors who have just completed their internship to those who have had highly responsible professional experience. The positions are located throughout the United States and in foreign countries. Starting salaries range from $7,510 to $12,770 a year. The major employers of medical officers in the federal government are the Army, Navy, and Air Force installations (civilian service); the Public Health Service; Indian Service Hospitals; the Food and Drug Administration; St. Elizabeths Hospital in the District of Columbia; and the Children's Bureau.

Federal medical officers have an opportunity to do challenging research work in helping to maintain national health and to search for the causes of human diseases. They also care for patients in hospitals, clinics, military establishments, and other government organizations. The greatest need in these establishments has been in the fields of general medicine and surgery, nutrition, public health, tuberculosis, venereal disease, roentgenology, pathology, radiology, physical medicine and rehabilitation, and psychiatry. Medical officers serve as consultants in the administration of state medical programs, conduct programs and supervise medical personnel in industrial establishments which are under the direction of federal departments, or conduct health programs in a federal agency. They also make medical decisions which affect the enforcement of federal laws and claims for compensation on the basis of physical and mental disability, and they perform many other types of administrative work. Doctors who desire further information regarding these positions should obtain a copy of Announcement 178 at a post office or from the U. S. Civil Service Commission, Washington 25, D. C. Applications will be accepted until further notice.

DEATHS

Auslander, Morris, New York City; University and Bellevue Hospital Medical College, New York City, 1908; veteran of World War I; since 1942 served on the local Selective Service Board; formerly on the staff of the Lutheran Hospital; died Jan. 5, aged 71.

Barlow, Edward Callistus Ⓜ Georgetown, Ky.; Pulte Medical College, Homeopathic, Cincinnati, 1901; veteran of World War I; died in the John Graves Ford Memorial Hospital Nov. 17, aged 82.

Barnebee, James William Ⓜ Kalamazoo, Mich.; Rush Medical College, Chicago, 1901; formerly practiced in Mendon, where he was health officer for many years; associated with the Bronson and Borgess hospitals; served as examining physician for the local Selective Service Board; died in the Bronson Hospital Dec. 19, aged 80.

Beasley, Thomas J. Ⓜ Indianapolis; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; veteran of the Spanish-American War; served on the staffs of the Methodist, Community, and Indianapolis General hospitals; died Dec. 30, aged 78.

Benkendorf, Richard Clark Ⓜ Bushnell, Ill.; Chicago Medical School, 1936; member of the American College of Chest Physicians and the American Trudeau Society; veteran of World War II; member of the city health department; on the staff of St. Francis Hospital in Macomb, where he died Jan. 8, aged 50.

Blau, Arthur Isidor, New York City; University and Bellevue Hospital Medical College, New York City, 1913; a senior public health physician with the city department of health; served as health officer in Harlem, in the Red Hook–Gowanus district of Brooklyn and in Jamaica, Queens, and also as health officer of the Borough of Queens; in 1947-1948 directed the Bureau of Health Education; past-president of the Greater New York Public Health Officers' Association; died in the Memorial Hospital Jan. 8, aged 67.

Brake, C. Bernard, Dearborn, Mich.; Detroit College of Medicine and Surgery, 1921; died Dec. 10, aged 68.

Brooks, Everett Hayden Ⓜ Bloomington, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1897; for many years practiced in Appleton; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; died Dec. 17, aged 86.

Brown, James Erroll Ⓜ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; an associate member of the American Medical Association; died Dec. 16, aged 79.

Brown, James Steven Sr., Hendersonville, N. C.; Northwestern University Medical School, Chicago, 1893; associated with Margaret R. Pardee Memorial Hospital, where he died Dec. 26, aged 92.

Burthe, Joseph Leopold, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1897; died in the Ochsner Foundation Hospital Dec. 30, aged 83.

Bushman, Louis Bernard Ⓜ Omaha, Neb.; John A. Creighton Medical College, Omaha, 1903; for many years on the faculty of his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; associated with St. Catherine's Hospital, Douglas County Hospital, and Creighton Memorial St. Joseph's Hospital, where he died Dec. 30, aged 81.

Carman, William L., Irwin, Pa.; Kentucky School of Medicine, Louisville, 1905; veteran of World War I; died in the Veterans Administration Hospital, Pittsburgh, Dec. 3, aged 81.

Chiles, William Wallace, Chesterfield, S. C.; University of Arkansas School of Medicine, Little Rock, 1927; veteran of World War I; died Dec. 16, aged 65.

Chung, Margaret Jessie, San Francisco; College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles, 1916; for a short time psychiatric criminologist for Illinois; at one time associated with Kankakee (Ill.) State Hospital; died Jan. 5, aged 69.

Crawford, Frank Wallis Ⓜ Holbrook, Mass.; Tufts College Medical School, Boston, 1909; veteran of World War I; past-president of the Norfolk South District Medical Association; past-president and charter member of the Randolph Rotary Club; associated with the Goddard Memorial Hospital in Brockton and South Shore Hospital in Weymouth; died Dec. 30, aged 76.

Ⓜ Indicates Member of the American Medical Association.

Critchfield, Charles Louis, Waverly, Ohio; Ohio State University College of Medicine, Columbus, 1938; formerly associated with the Orient (Ohio) State School; died Dec. 30, aged 46.

Crocker, Samuel H., Stantonsburg, N. C.; Kentucky School of Medicine, Louisville, 1894; served as mayor of Stantonsburg and as chairman of the school board; instrumental in organizing the Planters Bank and served as its first president; for many years a director of the Federal Land Bank of Columbia, S. C.; died Dec. 13, aged 91.

Croom, Gabe Holmes Ⓜ Asheville, N. C.; North Carolina Medical College, Charlotte, 1909; served overseas during World War I; died Dec. 26, aged 74.

Davis, John Joseph Ⓜ Brooklyn; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1894; died Dec. 10, aged 85.

Deich, Jacob Frank Ⓜ Boston; Tufts College Medical School, Boston, 1927; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the International College of Surgeons and the American College of Surgeons; served on the faculty of his alma mater; on the staffs of the Boston City and Beth Israel hospitals; died Dec. 28, aged 54.

DeLancy, Oscar Minton, Clovis, Calif.; Washington University School of Medicine, St. Louis, 1922; died Dec. 18, aged 63.

Dickson, Harry Ellis, Marietta, Ohio; Ohio State University College of Medicine, Columbus, 1914; died Dec. 27, aged 70.

Dieffenbach, Richard Hagen Ⓜ Newark, N. J.; born in 1883; Columbia University College of Physicians and Surgeons, New York City, 1904; member of the founders group of the American Board of Surgery; specialist certified by the American Board of Thoracic Surgery; member of the American Association for Thoracic Surgery and New York Thoracic Society; fellow of the American College of Surgeons; past-president of the Anatomical and Pathological Society of New Jersey; associated with Clara Maass Memorial Hospital, where he was for many years president of the staff, and the Essex County Hospital in Belleville, Alexian Brothers Hospital in Elizabeth, St. Mary's Hospital in Orange, Columbus Hospital, Martland Medical Center, St. Barnabas Medical Center, St. Michael's Hospital, St. James Hospital, Newark Eye and Ear Infirmary, and Presbyterian Hospital; member of the board of directors of the Bank of Commerce; died Jan. 2, aged 75.

Dredge, Homer Percy Ⓜ Sandstone, Minn.; Rush Medical College, Chicago, 1896; for many years health officer; served as president of the Pine County School Board; for many years member of the school board; at one time practiced in Belview and served as coroner of Redwood County; in 1955 was selected as the first member of the Sandstone Hall of Fame; died in the Asbury Hospital, Minneapolis, Nov. 27, aged 88.

Epeneter, Franz Joseph, Portland, Ore.; State University of Iowa College of Medicine, Iowa City, 1911; died in the Physicians and Surgeons Hospital Dec. 29, aged 69.

Fitzgerald, Don Felipe Ⓜ Wayzata, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; died at Lake Minnetonka Dec. 8, aged 91.

Fonvielle, William Bassette Ⓜ Rockford, Ill.; Howard University College of Medicine, Washington, D. C., 1928; member of the American Academy of General Practice; veteran of World War II; on the staff of St. Anthony Hospital; died Dec. 31, aged 59.

Fowler, Russell Story, Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1895; past-president of the Medical Society of the County of Kings, the Brooklyn Surgical Society, and the Clinical Society of Wyckoff Heights Hospital; specialist certified by the American Board of Surgery; founder, life member, and past-governor of the American College of Surgeons; honorary director emeritus of surgery at the Wyckoff Heights Hospital, where for many years he was chief surgeon; consultant, Methodist, Maimonides, and Bay Ridge hospitals; author of many books on surgery; died Jan. 5, aged 84.

Fraser, Noah Edward, Conway, Ark.; Memphis (Tenn.) Hospital Medical College, 1908; past-president of the Faulkner County Medical Society; on the staff of the Conway Memorial Hospital, where he died Dec. 21, aged 78.

Frazier, Harry Orwin Ⓜ Salt Lake City, Utah; University of Nebraska College of Medicine, Omaha, 1936; past-president and secretary of the Intermountain Ophthalmological Society and the Pan American Association of Ophthalmology; veteran of World War II; on the staff of the Latter-Day Saints Hospital; died Dec. 31, aged 52.

Geoghegan, Thomas Whitney, St. Paul, Minn.; University of Buffalo School of Medicine, 1925; medical director of the St. Paul Red Cross Program; served during World War II and was decorated for his services in the South Pacific; died Jan. 10, aged 57.

Gold, Bertha Benjamin, Jersey City, N. J.; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1897; vice-president and board member of the Hudson County Hebrew Home for Orphans and Aged; died Jan. 9, aged 84.

Grace, Joseph B., Bismarck, N. D.; John A. Creighton Medical College, Omaha, 1912; died Dec. 21, aged 77.

Groebner, Otto Andrew Ⓜ Sioux Falls, S. D.; University of Minnesota Medical School, Minneapolis, 1917; served overseas during World War I; on the staffs of the Sioux Valley and McKennan hospitals; died Dec. 21, aged 65.

Hamilton, Burke Coonley, New York City; Syracuse University College of Medicine, 1906; veteran of World War I; served with Red Cross commission to Balkan States; died in St. Vincent's Hospital Dec. 21, aged 77.

Harding, James Sylvester, Baltimore; George Washington University School of Medicine, Washington, D. C., 1924; on the staffs of Bon Secour Hospital and St. Joseph's Hospital, where he died Dec. 20, aged 60.

Hartmann, Richard Anthony Ⓜ Effingham, Ill.; Stritch School of Medicine of Loyola University, Chicago, 1951; member of the American Academy of General Practice; past-president of the Effingham County Medical Society; on the staff of St. Anthony Hospital; died in Hollywood, Calif., Jan. 1, aged 35.

Hollingshead, Lyman Benajah, Springfield, Ill.; Medico-Chirurgical College of Philadelphia, 1906; veteran of World War I; formerly practiced in Pemberton, N. J., where he served as mayor; died Nov. 18, aged 82.

Holmes, Hal Buck, Conway, S. C.; Medical College of South Carolina, Charleston, 1926; veteran of World War I; on the staff of the Conway Hospital; died in Myrtle Beach Dec. 27, aged 62.

Howard, Marion Edith, Cali, Colombia, South America; Johns Hopkins University School of Medicine, Baltimore, 1931; served as assistant physician at the Johns Hopkins Hospital and Dispensary; formerly an intern and resident at the New Haven (Conn.) Hospital; for many years on the faculty of Yale University School of Medicine in New Haven, Conn., where she was associate clinical professor of medicine, and associate physician, department of university health; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; died Jan. 5, aged 59.

Huff, Bolivar, Camp Verde, Ariz.; University Medical College of Kansas City, Mo., 1900; formerly associated with the Indian Service; died in the Good Samaritan Hospital, Phoenix, Dec. 5, aged 89.

Hurley, George Ira, Eugene, Ore.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; fellow of the American College of Surgeons; served overseas during World War I; on the staff of the Sacred Heart Hospital; died Dec. 31, aged 81.

Hurst, Julius Harold, Lubec, Maine; Yale University School of Medicine, New Haven, 1904; Columbian University Medical Department, Washington, D. C., 1903; veteran of World War I; fellow of the American Association for the Advancement of Science; formerly associated with the U. S. Public Health Service and Veterans Administration; died in the New England Baptist Hospital, Boston, Dec. 10, aged 85.

Johnston, Henry Vernon Ⓜ Pungo, Va.; Columbian University Medical Department, Washington, D. C., 1907; died in the Walter Reed Army Hospital, Washington, D. C., Dec. 21, aged 75.

Kobes, Herbert Richard Ⓜ Springfield, Ill.; Harvard Medical School, Boston, 1930; clinical associate professor of pediatrics, University of Illinois College of Medicine; specialist certified by the American Board of Pediatrics and the American Board of Preventive Medicine; member of the American Academy of Pediatrics and the American Public Health Association; director of the University of Illinois Division of Services for Crippled Children in Springfield since 1945; director of the Center for Handicapped Children at Research and Educational Hospitals; died Jan. 10, aged 54.

Koory, Shickrey B., Woodland Hills, Calif.; Creighton University School of Medicine, Omaha, 1907; at one time on the faculty of his alma mater; died in Van Nuys Nov. 6, aged 74.

Laguardia, Attilio, New York City; born Sept. 23, 1903; Columbia University College of Physicians and Surgeons, New York City, 1927; specialist certified by the American Board of Psychiatry; member of the American Psychiatric Association; formerly on the faculty of the Ohio State University College of Medicine in Columbus; assistant commissioner of mental hygiene for the state of Ohio from 1945 to 1947; from 1947 to 1949 chief of mental hygiene for the Veterans Administration office in Columbus, Ohio; for many years associated with the Rockland State Hospital in Orangeburg, N. Y.; on the staff of the Hillside Hospital; died in the University Hospital Jan. 5, aged 55.

Molliver, Henry Ⓜ Chelsea, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1933; on the staff of the Chelsea Memorial Hospital; member of the American Academy of General Practice; died in the Beth Israel Hospital Dec. 23, aged 54.

Perry, Julia Wygant, Forest Hills Gardens, N. Y.; Woman's Medical College of Pennsylvania, Philadelphia, 1891; died Dec. 17, aged 94.

Preiser, Samuel Aaron, New York City; Long Island College Hospital, Brooklyn, 1910; associated with Mount Sinai, Beth Israel, and Montefiore hospitals; died in the Bellevue Hospital Dec. 4, aged 74.

Reeves, John Herbert Ⓜ Chicago, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1896; veteran of World War I; died Jan. 14, aged 84.

Simmons, Albert Vander Veer Ⓜ Maplewood, N. J.; University and Bellevue Hospital Medical College, New York City, 1907; for many years on the staff of the Orange (N. J.) Memorial Hospital; died in Ballston Spa Jan. 4, aged 74.

Smith, Gilbert Elden Ⓜ Spartanburg, S. C.; University of Illinois College of Medicine, Chicago, 1934; specialist certified by the American Board of Radiology; on the staff of the Spartanburg General Hospital; died Dec. 3, aged 50.

Standish, James Herbert Ⓜ Hartford, Conn.; University of the City of New York Medical Department, New York City, 1895; on the courtesy staffs of Hartford and St. Francis hospitals; died Dec. 22, aged 88.

Sterrett, William Preston Ⓜ Humansville, Mo.; Ensworth Medical College, St. Joseph, 1900; past-president of the Wyandotte County (Kan.) Medical Society; served on the faculty of the University of Kansas School of Medicine in Kansas City, Kan., where he practiced for many years and where he was on the staff of the Bethany Hospital, where he died Dec. 19, aged 99.

Strack, Gustave Ⓜ Brooklyn; University and Bellevue Hospital Medical College, New York City, 1903; died in the Brooklyn Hospital Nov. 12, aged 83.

Swartz, George Krumrine Ⓜ Fort Myers, Fla.; born in Tusseyville, Pa., April 23, 1897; University of Pennsylvania School of Medicine in Philadelphia, 1924; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War I; formerly associated with the U. S. Public Health Service Reserve; at one time on the faculty of his alma mater and Baylor University College of Medicine in Houston, Texas; at various times affiliated with the Veterans Administration Hospital in Coatesville, Pa., on the staff of the Norristown (Pa.) State Hospital, Battle Creek (Mich.) Sanitarium, and the Missouri Baptist Hospital in St. Louis; died in the Lee Memorial Hospital Dec. 20, aged 61.

Thomas, Joseph Edward Ⓜ Plant City, Fla.; born in Studa, Pa., Oct. 30, 1921; Georgetown University School of Medicine, Washington, D. C., 1948; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; interned at St. Elizabeth's Hospital in Youngstown, Ohio, where he served a residency; formerly a resident at St. Vincent's Hospital in Jacksonville, Fla., and St. Thomas Hospital in Nashville, Tenn.; in 1952 called into service with the Air Force and served in the Azores; on the staff of the South Florida Baptist Hospital; died in the Veterans Administration Hospital, Bay Pines, Dec. 31, aged 37.

Thomson, Allen Milo, Santa Rosa, Calif.: University Medical College of Kansas City, Mo., 1898; a surgeon in the Navy during the Boxer Rebellion and the Spanish-American War; veteran of World War I; died Dec. 24, aged 82.

Tuohy, Edward Boyce Ⓜ Los Angeles; born in Duluth, Minn., March 17, 1908; University of Pennsylvania School of Medicine, Philadelphia, 1932; interned at the Ancker Hospital in St. Paul; went to Rochester, Minn., on Oct. 1, 1933, as a fellow in medicine at the Mayo Foundation; in 1935 changed to anesthesiology; on April 1, 1935, was appointed a first assistant in anesthesiology and on Oct. 1, 1935, was appointed to the staff of the Mayo Clinic as a consultant in anesthesiology; received the master of science in anesthesiology from the University of Minnesota in 1936; an instructor in anesthesiology in the Mayo Foundation, Graduate School, University of Minnesota in 1937, assistant professor in 1940, and associate professor in 1945; resigned in 1947 and accepted the appointment as professor of anesthesiology and head of the department of anesthesiology at Georgetown University School of Medicine in Washington, D. C.; later appointed clinical professor of surgery (anesthesiology) at the University of Southern California School of Medicine in Los Angeles; specialist certified by the American Board of Anesthesiology and a member of the board of directors from 1950 to 1956; veteran of World War II; promoted to the grade of lieutenant colonel in the reserve corps in 1954; delegate, section on anesthesiology, American Medical Association, 1957-1958, and member of its House of Delegates in 1949, 1952, 1954, 1956, and 1958; past-president of the American Society of Anesthesiologists; member of the International College of Surgeons, American College of Anesthesiologists, California Society of Anesthesiologists, American Society for Experimental Pharmacology and Therapeutics, American Association for the Advancement of Science, the Society of the Sigma Xi, the Alumni Association of the Mayo Foundation, the Nu Sigma Nu and Chi Psi fraternities; on the staffs of St. Vincent's, California, and St. John's hospitals, and the Hospital of the Good Samaritan; served as consultant in anesthesiology to the U. S. Naval Medical Center and the U. S. Public Health Service, and a senior consultant in anesthesiology to the U. S. Air Force; contributed more than 100 papers to the medical literature, chiefly on anesthesia; died Jan. 12, aged 50.

FOREIGN LETTERS

AUSTRIA

Parathyroid Insufficiency in Children.—At the meeting of the Society of Pediatrics in Vienna in December, Dr. H. H. Jesserer stated that although parathyroid insufficiency is rare in children it is of practical significance because of its misleading symptoms. The disease may occur in all stages of life, even in the neonatal period, and it may lead to epileptiform or tetanic convulsions. The epileptiform convulsions occur more frequently and often lead to an erroneous diagnosis. Later retardation of physical development; anomalies of the teeth; morbid changes of the nails, hair, and skin; or a lamellar cataract may develop and point to the correct diagnosis. All these changes can be prevented by the administration of dihydrotachysterol or vitamin D. The prognosis of this disease depends largely on an early diagnosis and appropriate treatment. If, because of an erroneous diagnosis, proper treatment is delayed, irreversible changes of hypoparathyroidal cretinism may occur.

Cervical Biopsies at Delivery.—At the meeting of the Society of Gynecology and Obstetrics in Vienna in December, Drs. V. Gruenberger and R. Ulm reported on cervical biopsy specimens taken from 110 women immediately post partum. These showed excessive hyperemia and edema, marked thinning of the pavement epithelium, hypertrophy of the mucosa, and round cell infiltration. Less than half of the specimens showed a pronounced decidual reaction. In 28 the border of the cylinder pavement epithelium was outside the opening of the cervix located at the margin of a glandular ectopia and in 22 it was within the opening of the cervix, since epidermization extended into the cervical canal. Atypical changes of the pavement epithelium were present in only eight patients. No malignant degeneration of the pavement epithelium was seen. In view of these findings the possibility of an involution of the atypical pavement epithelium up to the end of pregnancy is suggested.

BRAZIL

Wandering Spleen.—In January, at the 20th anniversary meeting of the Sanatorio São Lucas of São Paulo, Dr. E. B. Ribeiro gave a lecture on wandering spleen. He stressed the difficulties of diagnosis as the wandering spleen may occupy any part of the abdominal cavity, where it may be mistaken for a tumor. The patient usually goes to a doctor only when acute torsion develops. A thorough examination is not always possible because the severity of the symptoms may call for immediate operation. In the Brazilian medical literature, only six cases of wandering spleen with torsion of the pedicle have been reported. Dr. Ribeiro's patient (the seventh) was operated on, as generally happens, with the diagnosis of torsion of the pedicle of an ovarian cyst. The patient was a 15-year-old girl who several years earlier received a blow to her left hypochondrium. After that accident and since her seventh year she had been aware of a wandering abdominal tumor. Acute symptoms appeared only when the torsion occurred. When she was examined, a mass was felt in the left lower quadrant of her abdomen, disappearing into the pelvis. This condition is much more frequent in women than in men.

CANADA

Blood Transfusions and Jehovah's Witnesses.—Headline news was recently made by the refusal of members of Jehovah's Witnesses to let their children receive blood transfusions under any circumstances. The controversy is not new but has reached new heights. The current episode began early in November, when the son of a Witness was shot in the leg, lost a lot of blood, and required a blood transfusion as a lifesaving measure. The Children's Aid Society in Manitoba, where permission for this necessary measure was being withheld by the parents, wished to have the boy made their ward because of alleged parental neglect, but unfortunately the legal procedure involved delayed a decision until the boy had died. Soon afterward a lawyer told a panel of physicians that in seven or eight cases he had advised doctors in a similar situation to give a transfusion and risk a court action, since he believed that there was not one chance in 5 million of a doctor concerned being charged with assault. He said that he did not see how anyone could face damages after saving a life. This advice was frowned on by the secretary of the Canadian Medical Association, who pointed out that parents had a perfect right to accept or reject treatment offered, and that it would be difficult for a physician to state categorically that without a transfusion a certain patient would inevitably die. The secretary of the Canadian Medical Protective Association, speaking on the same

The items in these letters are contributed by regular correspondents in the various foreign countries.

panel, believed that a physician had no right to do anything to a child without the consent of the parent or guardian.

In mid-December this same problem arose in Toronto where at the Hospital for Sick Children a child with erythroblastosis required a transfusion and the parents, Jehovah's Witnesses, refused permission. When the situation had become desperate, a court awarded custody of the infant to the Children's Aid Society. Within four minutes of the announcement of the decision the first transfusion had begun, and the child's condition improved steadily. A plan by the counselor for the Witnesses to appeal the decision to the Ontario Supreme Court was dropped, but the case continued to excite argument in the press, with Bible scholars, ministers, rabbis, and lawyers all giving opinions, and with the likelihood that the precedent set will be followed on future occasions.

Hospital Insurance.—Well over 50% of Canadians are covered by government hospital insurance schemes. In recent months Ontario, which started its compulsory scheme on Jan. 1, enrolled over 90% of the population and introduced some additions to the original plan. For example it was agreed that patients in approved nursing homes would have their bills paid by the plan, and the government intends to use 600 vacant beds in tuberculosis sanitariums for care of chronic and convalescent invalids under the scheme. Moreover, it raised its payments to hospitals for outpatient visits from 30 cents to $1.50, as a measure toward making better use of outpatient departments and relieving the crowding of hospital beds. This is of particular benefit to teaching hospitals, in which costs of running outpatient departments are high (for a Toronto hospital costs are about $3.50 a visit and revenue about $1.30). Hospitals will receive from the government a special depreciation grant for 1959 of $150 per bed against debt retirement, future depreciation, and future expansion. Similar grants have been made in the past, but there was no certainty that they would continue. The aim of the new plan is to encourage hospitals to provide more accommodation.

Dental Services Insurance.—Organized medicine has long recognized the need for some form of insurance for medical care among the less privileged sections of the population and has also held that schemes for the provision of such services will function more efficiently if they are controlled by the profession than if they are controlled by the government. Dentists are now expressing similar sentiments, and at a November meeting the secretary of the Royal College of Dental Surgeons suggested a national health scheme including both medical and dental services. A plan has been operating in Saskatchewan for three-and-one-half years, and is being adapted for use in Alberta and Ontario in 1959, whereby a patient may receive necessary dental care and pay for it in installments without third-party participation. Patients arrange with their dentists about payment over an agreed period and are charged an initial service fee of $1 plus 30 cents a month if the account is under $150. Dentists are charged 1% on accounts remitted and a $35 membership fee. In addition, a welfare plan, with payment by the government, provides basic dental care for dependent children or dependent foster children qualifying under the Mothers and Dependent Children Act of 1957. Payment is at the rate of 70 cents a month for each child involved. The editor of the *Canadian Dental Association Journal* defended such schemes vigorously.

Thrush in Nurseries.—Harris and co-workers (*Canad. M. A. J.* 79:891, 1958) studied thrush (neonatal candidiasis) at the New Mount Sinai Hospital, Toronto, with a view to its elimination from the hospital nurseries. The departments of obstetrics, pediatrics, and pathology cooperated in this study, which involved 1,442 consecutive pregnant patients and their infants. Cultures were made from vaginal smears of all patients before preparation for labor, and cultures were made of oral swabs taken from all the infants on the first or third day and on the day of discharge. The incidence of vaginal candidiasis was 17.6%; oral cultures made from about 20% of the infants of these women were positive; and 11.4% suffered from thrush. Among those women from whom negative cultures were made the incidence of contamination was low. The use of antibiotics or douches was not a factor in contamination, but early rupture of the membranes appeared to have some protective effect on transmission from the vagina to the infant. Breast-feeding did not appear to increase the incidence of infection. Of 714 infants treated prophylactically with nystatin by oral instillation only 0.4% developed thrush, whereas of 728 control infants 4% developed this infection. The dose now recommended is 100,000 units instilled into the mouth on the second and fifth days of life. The last 615 babies so treated have all been free from thrush.

Q Fever.—In 1956, for the first time, a case of Q fever was reported and some time later it was pointed out that a large proportion of the provincial population appeared to have in their blood antibodies capable of complement fixation in the presence of the specific antigen of Q fever. Pavilanis and co-workers (*Canad. Pub. Health J.* 49:520 [Dec.] 1958) reported an epidemic in the little town of Princeville, Quebec, with a population of 2,700, in which over 33% of the workers at the local abattoir were involved (62 cases within 17 days), and nobody else. The illness was at first thought to be a Salmonella infection, but it did not respond to antibiotics, and serum agglutination tests were inconclusive, so the provincial epidemiologist was consulted. The clinical signs were those of an acute respiratory virus infection, and only employees handling the carcasses and viscera of slaughtered animals were affected.

Two teams, one for laboratory testing and another for veterinary investigation, were formed. The laboratory showed by serologic tests that the causative agent was Coxiella burnetii and this agent was also isolated from four sample of ewe placenta. It was also found that 9.9% of the bovine population of the province either was or had been infected with this agent. The sheep of the province were more infected than those in northern California, with a positive incidence of 59% in a series of 91 tested. The sheep parasite Melophagus ovinus seemed to be a vector.

Unions Consider Medical Plan.—On Jan. 15 a conference of Toronto trade union leaders appointed a committee to investigate the possibility of establishing a new medical care program, after union welfare experts had criticized existing medical plans as inadequate and recommended instead a group practice plan with salaried physicians as the most desirable type. The union specialists particularly criticized the major medical plans underwritten by commercial carriers. One spokesman said, "With the deductible and co-insurance features of these plans, we would estimate that the average Toronto trade unionist and his family would be paying the greater share of their medical costs out of their own pockets." He believed that there was insufficient emphasis in current plans on the maintenance of health or the prevention of illness. Although the federal-provincial hospital plan was praised, the absence of outpatient coverage was lamented. A deadline of 18 months has been set by the conference for a report and a second conference to put the program into effect. The idea is presumably to get a pilot scheme going in Toronto as a model for more widespread plans later.

Traffic Accidents.—A pilot study of persons injured in traffic accidents who were treated in the Montreal General Hospital and the Montreal Children's Hospital in a six-month period was made by Ruth McDougall (*Canad. M. A. J.* 80:18, 1959). Although this study could not be taken as representative of accidents in the city as a whole, since only 8.3% of all injured came to these two hospitals, it revealed the basic ignorance surrounding these common occurrences. While more passengers were treated than drivers, statistics do not show whether the passenger is in greater danger than the driver since the police do not keep figures for total passengers in such accidents. Although the risk to pedestrians appears to be greatest among the very young and the very old, there is no percentage estimation of the risk in these age groups. The commonest type of accident was a collision between two vehicles, and the greatest number of accidents occurred between midnight and 4 a. m., but no figures for traffic density by four-hour periods are available.

Of 294 such patients treated at the Montreal General Hospital 79.3% were treated as outpatients and 20.7% were admitted. Of the outpatients it appears that 43.5% did not really need hospital services. Only three fractures (fibula, maxilla, and a cervical vertebra) were missed. Of the 294 patients 1.2% had fatal, 19.8% serious, and 79% minor injuries. Only four patients were left with a permanent disability. Whereas among those 15 years of age or over only 31.1% were pedestrians, 77.4% of the children under 15 were pedestrians. The need for uniform accident reporting across Canada is stressed, so that areas of high incidence can be compared with those of low incidence.

Homosexual Transmission of Syphilis.—Early in 1957 the increase in infectious syphilis noted in other parts of Canada and the United States suddenly became evident in British Columbia, and it was found that increasing numbers of male patients at the venereal disease clinic in Vancouver were admitting to male contacts. There had been an epidemic of venereal disease in this area among homosexuals in 1951. In 1957, 77% of men treated for early syphilis in Vancouver clinics admitted homosexual activity, and there were a number of cases of gonorrhea as well. In reporting this significant change in disease pattern Larsen (*Canad. M. A. J.* 80:23, 1959) pointed out that homosexuals with venereal disease appear to be more promiscuous than their heterosexual counterparts and are therefore a greater potential menace. It is also likely that some contacts are being missed by private practitioners. The most effective method of dealing with this situation lies in the examination of the greatest possible number of contacts, which depends on cooperation of the patients.

Pneumocystic Pneumonia.—While over 2,000 cases of pneumonia due to Pneumocystis carinii have been reported from Europe, the total in the Canadian literature now stands at only 23. Berdnikoff (*Canad. M. A. J.* 80:1, 1959) recently described 14 cases from Montreal, giving full details for the last 3 in his series. He noted that the age incidence lay between 2 and 4 months, and that about 40% of cases were in premature infants. Debility due to previous infection or neurological disease seemed to be an important factor, and in each patient the illness started suddenly with periods of dry unproductive cough and signs of suffocation. Oxygen usually brought temporary relief to the cyanosis and tachypnea. There was no fever. A diagnostically significant feature may be the occurrence of a symptom-free period of a few days after the onset of the disease, which was observed in seven of the author's patients. Auscultatory signs were usually absent, though pneumothorax was not rare. Leukocyte counts and roentgenograms were diagnostically unreliable. All the 14 patients in this series died, although some patients are reported to have recovered. In the same issue (*ibid.* 80:35, 1959) Junger and Wyllie of Montreal report another case of pneumocystic pneumonia that was diagnosed during life, in a 3-month-old premature child with brain damage. A chest roentgenogram was recognized by a European physician as typical of interstitial plasma cell pneumonia due to this organism. The child was cyanotic but without fever or abnormal physical signs in the chest. Death the next day led to autopsy confirmation of the diagnosis.

DENMARK

Bronchial Asthma in School Children.—Sven Fransen (*Acta Allergol.* 12:341-357, 1958) reported that for the school year 1949-1950 an incidence of bronchial asthma of 0.8% was found among school children in Copenhagen. The incidence was highest at ages 9 to 12 years. Over 33% were girls. The frequency of nonattendance increased gradually with the intensity of the disease. Many children had a high frequency of nonattendance, and about 20% had been absent from school for more than a quarter of the school year. With regard to knowledge, the children did well in spite of prolonged nonattendance; almost 33% were above average and less than 17% below. Over 25% of the boys and almost 50% of the girls were wholly or partly excused from physical exercise and sports. Chronic sequelae of the asthma in the form of deformity of the thorax, emphysema, and faulty carriage were seen in 17%. About 25% had not been referred for specialist treatment of the disease and the author considered that there was insufficient treatment of this disease among school children.

Epilepsy in Children.—Dr. S. Brandt (*Nordisk medicin*, Jan. 15, 1959) reviewed his experiences with 100 epileptic children who, after treatment in hospital, had been kept under ambulant observation. He studied their reactions under home conditions, noted the choice and dosage of drugs, kept a look-out for symptomatic epilepsy with a view to rendering air-encephalography unnecessary in some cases, and attempted by systematic blood counts to avoid untoward drug reactions. The epilepsy was symptomatic in 16 patients, cryptogenic and nonfamilial in 54, and cryptogenic but possibly familial in 30. In 30 the epilepsy had begun before the age of 2 years. Using the frequency of epileptic attacks as an index, the results of ambulant treatment were as follows: 53 were free from attacks, 19 were improved, and 28 were unchanged. These findings were, on the whole, confirmed by electroencephalography. The outlook appeared to be best for the children with symptomatic epilepsy and worst for those with defective intelligence and subject to different types of attack. Some of the children suffering from petit mal relapsed even after an interval of several years' freedom from attacks.

Can Routine Blood Counts Prevent Drug Reactions?—In *Ugeskrift for læger* for Jan. 15, Dr. T. K. With questioned the value of blood counts in the prevention of agranulocytosis, and the thrombopenias and hemolytic anemias induced by drugs. His scrutiny of the history of blood counts in this connection failed to reveal any solid basis for them, and it is significant that there is as yet no unanimity over the procedure to be followed. A craving to insure against a hematological mishap has made many take refuge in a laboratory test which has become hallowed by usage. It is not only of doubtful value, but may also create a false sense of security. Clinical control based on the vigilance of the patient is the only effective measure. At every consultation he must be reminded of the risk involved in taking the drug in question, and he must discontinue it at once and consult his physician on the development of fever, malaise, sore throat, or a rash. The physician may then arrange for a differential white blood cell count and, if necessary, he may repeat it frequently for about two weeks after withdrawal of the drug. Routine serial blood counts per se, however, are of such doubtful value and cause so much inconvenience to patient and laboratory that, in With's opinion, they should be abandoned entirely.

New Succinimide for Petit Mal.—The new succinimide, PM 680, was tested by Trolle and Kiörboe (*Nordisk medicin*, Dec. 11, 1958) for 16 months at the Rigshospital in Copenhagen and the Odense City Hospital on 34 children (aged 3 to 15 years) and 4 adults suffering from petit mal attacks or allied conditions. Among them were six who also suffered from grand mal attacks. The usual initial dose was one 250-mg. capsule of the drug once a day. Every second or third day the dosage was increased by 250 mg., and for children between 10 and 12 it was usually 2 Gm. daily, given in three doses during the day. In some patients the dosage was much higher without definite side-effects. In some it took several months to determine the optimal dosage. Fourteen patients were completely relieved of their attacks, and classification of the patients according to the duration of their ailments showed that those fared best whose illness had lasted less than five years. The four adults did not fare well. Electrocardiograms in 6 of 37 patients became normal and in 18 showed marked improvement. A good correlation was established between the electrocardiographic and clinical findings. There were no side-effects necessitating withdrawal of the drug, and no abnormal changes developed in the blood periodically submitted for leukocyte counts. In addition to the 14 patients who became seizure-free, 17 showed a 50 to 99% reduction in seizure frequency. Only seven showed no improvement. In several patients the drug was found to be superior to earlier succinimide preparations and to produce fewer undesirable side-effects.

Surgery in the Elderly.—In 1946, the proportion of the population of Copenhagen aged 70 years or more was 4.8%. In the same year, 3.6% of the patients in department A of the Bisperbjerg Hospital were in this age group. There were thus fewer elderly patients than might be anticipated from the age distribution of the population. Ten years later the situation was reversed. The elderly inhabitants had risen to 6.8% and the number of such patients in hospital had risen to 9.2%. As a result, hospital mortality has risen. In the same decade the number of hospital patients over 70 and regarded as operable had risen from 25 to 50%, according to Dr. E. Amdrup and co-workers (*Danish Medical Bulletin,* December, 1958) who noted that twice as many of these patients are now operated on as were so treated in 1946 and the operative mortality has fallen. It must be anticipated that more and more patients over 70 will require operation. Indeed it would seem that old age is now hardly ever a contraindication per se for surgical treatment.

GERMANY

Iron-Binding Capacity of the Serum.—Lange and Oberhoffer (*Deutsches Arch. klin. Med.* 204:697, 1958) stated that the serum iron plays an important role in the differential diagnosis of diseases associated with jaundice. Clinical trials were conducted to determine the iron-binding capacity (FeBC) of serum in hepatic disease and in health. The test included 60 patients with hepatitis (maximum icterus), 26 with hepatic cirrhosis, 25 with obstructive jaundice, and 60 healthy controls. Uncomplicated acute hepatitis was found to be characterized by marked hypersideremia. The maximum FeBC was also increased in most patients, although less markedly. The latent FeBC was below normal. The serum iron level was below or within normal limits in most patients with obstructive jaundice. The maximum FeBC was reduced and the latent FeBC was normal in 17 of the 25 patients.

In those with cirrhosis, the serum iron pattern was irregular. There were normal as well as lowered and slightly increased values. The maximum FeBC was usually markedly lowered and the latent FeBC was reduced in 23%. The pattern of these values may be of diagnostic and, perhaps, prognostic importance. Intercurrent infections may give misleading values, as these processes are not liver-specific. The observed increase of maximum FeBC in patients with hepatitis has not yet been explained. The decrease of FeBC in chronic diseases may be due to disturbance of transferrin synthesis. In acute breakdown of hepatic function, a marked decrease of FeBC may occur, which may explain the abrupt fall of the serum iron level.

Parathyroid Tetany.—Tetany not only consists in spasm but also in other symptoms included in the term latent tetany. The serum calcium level in parathyroid deficiency is important. The fact that most tetanic patients have normal blood calcium levels (69 of 71 patients) gives rise to the question of whether these patients also have a parathyroid deficiency. K. W. Essen (*Deutsches med. J.* 9:410, 1958) believes that a subthalamic tetany center, which directs neuromuscular excitability of the periphery, may be excited by hypocalcemia (parathyroid deficiency) as well as by alkalosis (hyperventilation or loss of chlorine and acid), organic cerebral lesions, and constitutionally or dispositionally lowered excitability threshold (tetanic manifestations after stress).

The acute tetanic attack can be interrupted by the intravenous injection of a simple calcium salt, but complex calcium salts have not proved effective. For long-term treatment of hypocalcemic tetany, dihydrotachysterol and vitamin D are useful, while injections of parathyroid hormones are superfluous. In contradistinction to other authors, Essen concluded from the good results he obtained that dihydrotachysterol should also be used to treat normocalcemic forms of tetany in order to compensate a partial parathyroid deficiency (without hypocalcemia), to correct an alteration of the acid-base equilibrium of central origin, and to correct the ultrafiltrable serum calcium.

Prednisone for Tuberculosis.—H. D. Renovanz (*Ärztl. Wchnschr.* 13:805, 1958) attempted to determine in vitro and in vivo, whether an alteration of sensitivity occurs in resistant strains of Mycobacterium tuberculosis under the effect of cortisone and its derivatives. He found that there are no differences in the type and course of tuberculosis between sensitive and resistant strains and that no alteration of sensitivity of resistant strains occurs. He treated 50 tuberculous children and adolescents under tuberculostatic protection with prednisone. Marked improvement was achieved in 27 and complete radiologic remissions occurred in 8 of these. The condition remained unchanged in seven, and in five only the more recent, inflammatory perifocal patches receded. In the others there was a distinct aggravation of the disease. In one patient a reactivation occurred during treatment and in five others it occurred four to eight weeks after termination of treatment. Adjuvant treatment with steroid hormones is recommended for extensive tuberculous changes of recent origin in childhood and adolescence if the tuberculous changes have proved resistant to specific therapy. With a dosage of 10 to 20 mg. daily for 45 days, which is gradually withdrawn with the use of ACTH, nonspecific side-effects are not to be expected. Prerequisites are adequate tuberculostatic protection and regular clinical and radiologic controls to detect any new activation early.

Antibacterial Substances in Tissue.—H. Stein (*Beitr. Klin. Tuberk.* 118:314, 1958) stated that the body fights invading microorganisms mainly by serum antibodies and phagocytes. Interest is further attached to the question of how far antibiotic powers of the tissues play a role in combating various pathogens. The author's studies showed that liver tissue possessed remarkable bactericidal powers against Staphylococcus pyogenes var. aureus and Pseudomonas aeruginosa, while distinct inhibition or destruction of Escherichia coli was rare. There were marked differences in antibacterial activity in the liver from various mammals. Although the role of the individual factors relative to the whole antibacterial defense mechanism has not yet been fully explained, the author's investigations indicate that the body is capable of developing antibacterial substances that are comparable to antibiotics.

Vitamin A and the Pancreas.—M. Gülzow (*Ärztl. Wchnschr.* 13:597, 1958) reported that vitamin A deficiency may result from absorption disorders in pancreatic disease associated with digestive insufficiency, but it is rare in adults. Intraduodenally or intramuscularly administered vitamin A in doses of 40,000 units elevated pancreatic secretion. An excretory function test largely confirmed the stimulation of secretion, which occurred in two phases. Parallel with the secretory impetus there was frequently an enzymatic derangement. Examination of the serum diastase after intramuscular injection of vitamin A in 93 persons revealed fluctuating values not only in patients with pancreatitis but also in those with hepatic disease, diabetes, epigastric disease, and some without epigastric disease but with disturbance of equilibrium. In clinically proved pancreatic disease, on the other hand, the reaction sometimes fails to occur. In health the serum ferment reaction was less frequent (16%) when 210 tests, using mecholyl, were made. These tests suggested abnormal pancreatic function. Vitamin A, stimulating pancreatic secretion, is indicated for the treatment of subsiding acute pancreatitis. The mild pancreatic sialorrhea was considered as advantageous as the bile-flow in certain hepatic diseases.

Cancer Caused by Arsenic.—Occupational contact with insecticides and fungicides containing arsenic and the use of arsenic for certain skin diseases and anemia often cause cancer of the skin and internal organs. W. Braun (*Deutsche med. Wchnschr.* 83:870, 1958) reported a series of 16 vine-growers who handled large amounts of arsenic-containing insecticides between 1925 and 1942. Those who had drunk wine regularly developed nine inoperable bronchial carcinomas, three cases of epidermoid carcinoma, one carcinoma of the bile duct, one malignant tumor of a cervical lymph node, and three prickle-cell cancers of the skin, in addition to typical arsenical keratoses. The author also observed two cancers resulting from arsenical treatment. He further reported on three vine-growers with cancer of the lung, not presenting with cutaneous symptoms, after the use of arsenic, and 14 vine-growers with cancer of various organs in whose case histories contact with arsenic was not recorded but had probably taken place. Braun agreed with other authors than arsenic is a dangerous cancerogenic agent and that only in exceptional cases should a physician prescribe it.

Side-effects of Antibiotic Treatment.—H. Dennig (*Deutsche med. Wchnschr.* 83:1849, 1958) reported that of 170 patients treated with penicillin 5 cases of allergic exanthema occurred. Streptomycin caused one local reaction in a series of 50 patients. No vestibular or cochlear damage was observed. Streptomycin and penicillin combined gave rise to 6 cases of allergic exanthema in a series of 220 patients. The symptoms subsided after withdrawing the drugs. Of 117 patients treated with tetracycline, 1 case of exanthema and 6 of diarrhea occurred. Of 50 patients receiving chloramphenicol, 2 developed exanthema, 2 diarrhea, and 1 a fungus infection which may have been responsible for the patient's death. Erythromycin was given to 30 patients and was well tolerated by all. Of 11 patients receiving oleandomycin, only 1 complained of nausea. Of 76 taking tyrothricin inhalations, only 1 had an itching exanthema, which disappeared after administration of soventol and calcium. Dennig concluded that serious side-effects occur only in the form of enterocolitis (5% of those treated with tetracycline and 4% of those treated with chloramphenicol). Penicillin shock, severe dermatitis, and aplastic anemia were not seen in these series. The author emphasized that the drawbacks of antibiotic therapy are negligible when compared to the advantages.

NORWAY

Antistaphylolysin in Children with Asthma.—Harnaes and Borgen (*Acta Allergol.* 12:336-340, 1958) determined the antistaphylolysin titers of 113 asthmatic children. Elevated values were significantly more frequent than in the 58 nonasthmatic patients in the same age range who were used as controls. The skin-negative patients suffering from asthma of supposed bacterial origin and the truly allergic skin-positive children did not differ significantly, but a tendency toward increased values was noted in the former. The authors considered the possibility of an increased antibody-producing tendency per se among the allergic children.

SWEDEN

Lupus Erythematosus.—C. Ekelund (*Acta rheumatol. scandinav.* 4:172-177, 1958) examined 226 persons and found the gamma globulin to be increased in all those who showed a fairly strong positive reaction to the *p*-toluenesulfonic acid test, but the gamma globulin was found to be increased also in several of those who gave a negative or only weakly positive reaction. Ekelund stated that clinically the patients with a strongly positive reaction were often found to have either systemic lupus erythematosus or florid rheumatoid arthritis. Of 10 with L. E. cells the test was either negative or only weakly positive in 5, while in 165 patients with rheumatoid arthritis the reaction was positive in 55, though usually only weakly positive. False-positive reactions were also obtained in patients with myeloma and those with hepatic cirrhosis. The test cannot be regarded as a reliable tool for differentiating between lupus erythematosus and rheumatoid arthritis. The author concluded that perhaps there is no sharp border between these two diseases.

Steroids for Asthma.—Hans Arnoldsson (*Acta allergol.* [supp. 6] 12:1-190, 1958) reported that between January, 1953, and June, 1958, about 1,000 asthmatics were treated at the Allergy Clinic in Gothenburg, Sweden. Of these 161, with an average age of 54 years and a mean duration of asthma of 15 years, had endogenous bronchial asthma of such severity and intractability that corticoid therapy was considered essential. The patients were treated with ACTH and corticosteroids and given suitable bronchodilators and expectorants. The response to this preliminary course was excellent in 65.2%, good in 25.5%, and poor in 9.3%. Other forms of treatment were applied as a control measure to 26 and 43 received a placebo instead of prednisone. In two control series, comprising 69 patients, a recurrence of asthma of a degree requiring resumption of corticosteroid therapy occurred within four weeks in 40.5% and within eight months in 98.5%. To the treated series of 92 patients, 63 transfers were added from the control series and 11 were lost to the study. At the end of the investigation the longest duration of therapy was almost six years and the shortest 8 months (average 25 months). The response to therapy as judged by its effects on the severity of the asthma, working capacity, and relapse rate varied from good to excellent. At the end of the investigation 37.5% of the patients were free of asthma, 42.3% had mild symptoms occasionally, and 20.2% had moderate to severe asthma. Before therapy 89.5% of the patients had severe asthma and 10.5% moderate asthma.

The incidence of salicylate hypersensitivity among the patients in the treated series was 18%. The clinical response to long-term corticosteroid therapy of the salicylate-sensitive patients was favorable and they seemed no more resistant to such therapy than any other patients with bronchial asthma. Side-effects were cardiac and circulatory disturbances, aberrations of water and electrolyte metabolism, neurological and psychiatric manifestations, peptic ulcer, allergic reactions to ACTH, osteoporosis, and adrenocortical hypofunction. Seventeen patients between 48 and 78 years of age had signs of myocardial disease before the commencement of therapy, and some required maintenance doses of digitalis. Four of them had a myocardial infarction, but while therapy was in progress cardiac diseases definitely attributable thereto were not seen in any of these patients.

More than 800 determinations of serum sodium and potassium levels were made. About 96% of the sodium levels and more than 99% of the potassium levels were within the normal range. Weight increases, frequently marked, were common. Most of these increases could be ascribed to improved appetite resulting from better general health and a sense of well-being accompanying relief from symptoms. The author concluded that ACTH or corticosteroids could be given in minimal effective doses for several years without sodium restrictions or supplementary potassium. The so-called withdrawal syndrome was not observed, and the adrenal cortex responded adequately to various stressful stimuli without special therapy other than extra cortisone before and after major operations. Considering that 89% of the patients with osteoporosis were postmenopausal women, it seemed advisable to provide adjuvant treatment with a combination of androgens and estrogens for such patients on long-term ACTH or corticosteroid therapy.

Hypersensitivity to Phenylcarbinol.—B. Lagerholm and co-workers (*Acta allergol.* 12:295-298, 1958) were unable to find any report of hypersensitivity to phenylcarbinol used as a preservative in vitamin B_{12} solutions for injection. They observed a 28-year-old patient with arthropathic psoriasis who was given a course of vitamin B_{12} injections. The preparation contained 15 mg. of phenylcarbinol per milliliter as a preservative. Both the skin and the joint changes responded favorably, but after some time a regression occurred with increased joint distress, itching, pronounced reddening of the psoriatic lesions, and urticaria. Repeated thrombocyte tests with the selected brand of vitamin B_{12} made the platelet count drop heavily, from 439,000 to 45,000 in 60 minutes. Subsequently the patient underwent a course of treatment with pure, unpreserved vitamin B_{12}. This produced no untoward reactions. The negative thrombocyte test with pure vitamin B_{12} and the absence of untoward reactions while the patient was receiving pure vitamin B_{12} constituted further evidence that phenylcarbinol was the causative agent.

Asian Influenza.—An epidemic of Asian influenza occurred in Sweden in the period September, 1957, to April, 1958, with the peak morbidity in November, 1957. B. Körlof and co-workers (*Nord. med.* 60:1704-1706 [Nov. 27] 1958) estimated that about one million persons were affected, the highest incidence being reported among school children and Army personnel. The number of deaths from the influenza or its complications was highest in children below the age of 16 years and in persons over 61. The cause of death in most cases was pneumonia. The bacteria most commonly found in the lungs on autopsy were Staphylococcus pyogenes var. aureus and Escherichia coli.

Leo Heller and co-workers in the same issue reported that the antibody responses of volunteers inoculated with decreasing dilutions of a monovalent formalinized Asian influenza vaccine, prepared at the State Bacteriological Laboratory in Stockholm, were determined by the hemagglutination-inhibition test. In spite of the low hemagglutinating capacity of the vaccine strain (A/Singapore/1/57) even extremely small doses of the vaccine gave 11 to 22% serologically positive results after one and 55% after two injections. A dose of 1,500 hemagglutination units produced an antibody response after one injection in almost all subjects. Another vaccine preparation with a high hemagglutination titer was tested in a field trial on more than 1,000 recruits in an attempt to perform a direct titration of the protective effect of the vaccine. The protection rates found for doses of 2,000 hemagglutination units each were 69 to 86% for two and 57 to 78% for one injection. The corresponding figures for doses of 400 hemagglutination units each were 45 to 54% protection after two doses and 29 to 45% after one.

Proton-Beam Therapy.—Prof. L. Leksell and co-workers of the Gustaf Werner Institute for Nuclear Chemistry at Uppsala described the destruction by proton irradiation of a small cerebral tumor in a man aged 54. A beam of protons from a synchrocyclotron was focused on the tumor after its careful spatial localization by elaborate stereotaxic methods. Protons, unlike electrons and roentgen rays, are not widely scattered in the tissues, and as they give up their energy on reaching their target their effect can be localized to a small, preselected area of tissue. The procedure, being painless, required no anesthetic. The patient's head, which was fixed by clamps, was rotated for each exposure so that the proton beam could strike the target area from different angles. Forty exposures, each lasting 30 seconds, were given. The position of the tumor relative to the path of the beam was checked after each exposure to prevent normal brain tissue from being damaged. The patient was 80 ft. from the synchrocyclotron, from which he was separated by two 6-ft. walls. The beam was led from the synchrocyclotron through a tube 60 ft. long passing through the walls and focused by four lenses. The authors directed operations from a control room in which the patient was seen on a television screen, and they communicated with him by means of a microphone system. These elaborate screening precautions were necessary to prevent excessive radiation reaching the patient and the operators.

UNITED KINGDOM

Gastrotonometry.—In the course of treatment in a respirator it is essential that ventilation be controlled by adjusting the apparatus from time to time. The best guide to control is the carbon dioxide tension (pCO_2) of arterial blood, the determination of which involves arterial puncture and special blood storage. From studies made on over 400 patients in respirators Boda and Muranyi (*Lancet* 1:181, 1959) concluded that the pCO_2 of arterial blood could be deduced with reasonable accuracy from the intragastric pCO_2, which they found runs parallel to it and is usually 2 to 4 mm. Hg higher. For the determination of the intragastric pCO_2, termed gastrotonometry, they introduced through the nose into the stomach a thin-walled rubber balloon under 0.05 mm. thick and attached to polyethylene tubing. Not less than two hours after the last meal the balloon is filled with 20 ml. of room air through the tube, which is then sealed off. Gas in the stomach diffuses into the balloon. After equilibrium is established (about two hours) the air is sucked from the balloon into a suitably oiled syringe and its pCO_2, as well as that of the expired air, is measured by an infrared absorption method.

The authors found that in hyperventilation the gastric pCO_2 decreased, while in hypoventilation it increased. When ventilation was adequately adjusted, and there was no respiratory complication, the gastric pCO_2 was close to but a little higher than that at the end of respiration. In hyperventilation and in the presence of respiratory complications the difference between the gastric pCO_2 and that at the end of expiration increased. During treatment pCO_2 measurements indicated the onset of pulmonary complications. Gastrotonometry was found to be a simple and reliable method for the routine control of artificial respiration, particularly for patients being nursed in a respirator.

Pneumonoconiosis.—The National Coal Board's chief medical adviser announced that every British miner will be entitled to have a roentgenogram of the chest at least once every five years. The Board has purchased nine mobile x-ray units as part of its campaign against pneumonoconiosis in miners. It is expected that as a result of improved diagnosis the reported incidence of pneumonoconiosis will rise, but after the introduction of measures to suppress the disease such reported incidence should fall.

Television and the Child.—The rapid growth of television in the last 10 years has evoked much controversy over its effects on children. In 1954 Dr. Hilde Himmelweit and co-workers investigated the problem on behalf of the Nuffield Foundation. Their findings have been published in a booklet entitled "Television and the Child." They found that most children, unlike many adults, viewed selectively an average of about 12 hours of programs weekly. Other mediums of entertainment, such as cinema and radio, tended to suffer in competition. It was found that the more intelligent the child the less time he spent watching television at the expense of other pursuits. Television made less impact on those children leading a full and active life. The child television addict was typically one with personality problems, shy, poorly adjusted, insecure, and handicapped in emotional relationships. Television offers an escape from poor social adaptation, but it creates a vicious circle, because the more these withdrawn children watched it the less they were encouraged to overcome their emotional difficulties. Excessive viewing was the result of personality defects rather than the cause of them. For the correctly oriented child, games, hobbies, and social pursuits retained their attraction and television took second place.

It is difficult to know what effect television has on the child's mind. As many as 75% in the sample voted in favor of adult programs, particularly plays dealing with crime. Westerns were popular. They evoked little anxiety or aggression in spite of their usual background of violence, which is generally stereotyped. Adult plays depicting violence and conflict in human relations were more likely to make an unfavorable impact on the child's mind. Dr. Himmelweit considered that parents as well as television producers have a duty in controlling what the child sees. The investigation showed that television had little effect on the sleep pattern of the average child by causing overexcitement, anxiety, or keeping late hours. Emotionally insecure children might be affected, as they would be by the cinema. Really late bedtimes were no more common among child viewers than among child nonviewers. The inquiry also discredited the popular misgivings about television as a cause of listlessness, morning tiredness, and lack of concentration at school. Television even stimulated interest in reading in some children. Television was not found to make children more passive. No loss of initiative or dulling of the imagination was observed. It did, however, stimulate passive rather than active interests.

Smoking and Disease.—Most examinations of the association between smoking and disease are based on a comparison of the smoking habits of persons who have a specific disease with those of a control group. This procedure has been criticized on the grounds that the controls, however carefully selected, might not be strictly comparable. To overcome this objection Edwards and co-workers examined smoking habits and diseases present in a representative sample of the population (*Lancet* 1:196, 1959). In this way it was possible to compare the incidence of specific diseases in smokers and nonsmokers, rather than the frequency of smoking in affected persons and controls. A medical examination and interrogation of the smoking habits of 1,737 men over the age of 60 years was made. It was found that with increasing age the proportion of cigarette smokers decreased (from 55% in the men aged 60 to 64 years to 22% in those aged 85 and over), with a corresponding increase in the proportion of pipe smokers (from 12 to 50%). At the same time the total amount of tobacco smoked either as cigarettes or in pipes decreased with increasing age. Men of professional and related occupations smoked less than unskilled workers.

Data were obtained on eight of the commonest diseases or disabilities: defective hearing and vision, hypertension, chronic bronchitis, coronary artery disease, arthritis, peptic ulcer, and hernia. Of these hypertension, bronchitis, and peptic ulcer were found to be consistently associated with smoking habits. Hypertension, defined as a diastolic pressure above 100 mm. Hg or a systolic pressure above 200 mm. Hg, was commoner in nonsmokers than in smokers. In the case of cigarette smokers the incidence was inversely related to the number of cigarettes smoked daily. The frequency of hypertension in pipe smokers was intermediate between that of cigarette smokers and nonsmokers. On the other hand the incidence of bronchitis and peptic ulcer was higher in cigarette smokers than in pipe smokers or nonsmokers. The frequency of both diseases increased with the numbers of cigarettes smoked. Both diseases were commoner among men in poorly paid than in well paid occupations, but the effect of smoking appeared to be independent of social class. In all social classes the risks of chronic bronchitis and peptic ulcer were substantially increased by smoking, particularly cigarettes. For all social classes the incidence of peptic ulcer was higher in cigarette smokers than in pipe smokers and nonsmokers.

Unilateral Amblyopia.—Dr. R. Cole of Nottingham found unilateral amblyopia, colloquially known as lazy eye, to be present in 537 of 10,000 National Health Service patients (*Brit. M. J.* 1:202, 1959). In 1% of all patients examined one eye was blind, and in another 2% vision was so poor as to be useless. Amblyopia was considered to be present if visual acuity was less than 6/12 in the absence of disease. It was classed as unilateral if the other eye could read the letters two lines further down the Snellen chart than the amblyopic eye. Translated into general terms the findings suggested that of every 1,000 children born 53 fail to develop normal binocular vision. The left eye was more often involved than the right. Unilateral amblyopia often goes unnoticed until the good eye is affected by disease or injury or until the patient's vision is thoroughly examined.

The higher the intelligence of the patient and the more skilled his occupation, the greater the disadvantage of a nearly blind eye and lack of stereoscopic vision. Unilateral amblyopia results in a great waste of man power. Its economic and social disadvantages are equally serious, particularly if anything happens to the sound eye. Unfortunately the condition develops in infancy and early childhood and may be permanently established by the time the child starts school. Amblyopia primarily affects form vision but not the perception of light or its location, and for this reason it often goes unnoticed. The only way to attack this disability is to examine all children early and regularly and not wait until they go to school.

Dexamethasone.—Metabolic studies on dexamethasone, a new cortisone-like hormone, were made by Slater and co-workers (*Lancet* 1:173, 1959). This drug has been reported to have greatly increased anti-inflammatory action with less disturbance of carbohydrate metabolism than cortisone produces. Patients receiving it were given specially prepared diets of known composition. Fasting blood samples were taken twice a week for electrolyte, sugar, urea, plasma protein, calcium, and cholesterol level estimations, and daily urine and weekly fecal collections were made. Estimations were made of fecal sodium, potassium, nitrogen, and calcium levels, and urinary protein and creatinine levels. After a suitable control period 1 mg. of dexamethasone was given to the patients every six hours. In addition, adrenal suppression studies were made on normal subjects. It was concluded that dexamethasone did not produce sodium retention, but in some patients it greatly increased cell catabolism, with negative potassium and nitrogen level balance. Its action on calcium metabolism appeared to differ from that of cortisone and prednisone, and it was suggested that it should not be used to treat patients with hypercalcemia. The adrenal-suppressing and diabetogenic actions of dexamethasone were comparable to those of cortisone and other currently used steroids. There appeared to be no justification for claims that it is free from side-effects. The clinical effect of dexamethasone was variable in patients suffering from the nephrotic syndrome.

Sex Reversal in the Newborn.—The detection of sex reversal in apparent males has been facilitated by the sex chromatin test. Moore attempted to estimate its incidence by determining from oral smears the chromosomal sex of infants born in a large general hospital (*Lancet* 1:217, 1959). Smears from 3,715 babies—1,911 boys and 1,804 girls—were prepared by scraping the oral mucosa with a sterile nickel spatula, smearing on a slide, fixing with ether and alcohol, and staining with cresyl violet. Of the 1,911 anatomically male infants tested 5 showed female-sex chromatin in the cell nuclei. The anatomic sex was unknown to the observer who examined the slides. The pregnancies of the mothers of these infants were normal, the external genitalia were male in appearance, and the testes had descended. The proportion of nuclei counted in the smears establishing female-sex chromatin varied from 53 to 64%, which is within the range found in the nuclei from anatomically normal girls. All the 1,804 girls were confirmed as genetic females.

The five apparent boys with female-sex chromatin were regarded as cases of female-to-male sex reversal. The incidence was 0.26%, which would correspond to about three cases in every general practitioner's list. Moore suggested that there may be an abnormal metabolism of maternal or placental hormones during pregnancy, resulting in the formation of hormones with an androgenic action. If this occurs early enough they might cause the indifferent gonads of female embryos to develop as testes, with masculinization of accessory sex organs.

Ferguson-Smith examined the frequency of female-sex chromatin-positive micro-orchidism in 663 prepubertal boys attending schools for the [illegible] (*Lancet* 1:219, 1959), which was 1.2%. It is well known that a mental defect is often present in cases of female-to-male sex reversal. In all the cases seen testicular biopsy showed tubular hyalinization and a great reduction in spermatogonia.

CORRESPONDENCE

PHYSICAL FITNESS

To the Editor:—An article "Role of Pediatrician in Physical Fitness of Youth" by Lane appeared in THE JOURNAL (169:421-427 [Jan. 31] 1959). Just as any minister is against sin, any physician is in favor of physical fitness. Many of us deplore the overemphasis which has been placed on this segment of fitness in the last several years and still more resent the implication that the Kraus-Weber tests are a measure of anything more than some functions of a few muscle groups. At the Fort Richie meeting of the President's Citizens Advisory Committee on the Fitness of American Youth, the Special Interest Work Group on Health Services overwhelmingly voted down the suggestion that the Kraus-Weber tests, or any other available tests, could be taken as a scientific measure of "fitness." I question the advisability of reactivating this controversial question when the emphasis on the physical is just beginning to subside to its proper level.

I would like to emphasize that I strongly approve of physical education and think a properly organized program should exist not only in every school but also in every home. The organization of such programs should include recognition of the physiological needs of the persons involved and not be based on chronological age, as is so often the case.

THE STARCH TOLERANCE TEST

To the Editor:—An article by Nugent and Millhon, entitled "Clinical Evaluation of the Starch Tolerance Test," which appeared in THE JOURNAL (168:2260-2262 [Dec. 27] 1958), deserves comment. This test was proposed by Althausen and Uyeyama (*Ann. Int. Med.* 4:563-575 [Sept.] 1954) for the diagnosis of pancreatic disease. They used soluble starch as prepared by Lintner. Nugent and Millhon used both soluble starch and corn starch. Both are practically raw starch. The mixture is most unpalatable. The maximal rise in blood sugar level after the oral ingestion of 100 Gm. of glucose was compared to the rise after the oral ingestion of 100 Gm. of starch, and conclusions were drawn from the difference. In some cases paradoxical results were obtained. In one patient in whom the pancreatic duct was completely obstructed the test gave negative results. In another patient in whom the proximal two-thirds of the pancreas was normal, the test was strongly positive.

This test has one serious defect, namely, the use of raw or partially boiled starch. This is strikingly illustrated in the observations of Rosenthal and Ziegler (*Arch. Int. Med.* 44:344-350 [Sept.] 1929). They found that equal amounts (50 to 75 Gm.) of well-cooked starch (potatoes) and dextrose produced identical blood sugar curves, but orally administered soluble starch, also prepared according to Lintner, produced no rise in the blood sugar level of normal persons or diabetics. This is not to say that raw starch is not completely digested in the human intestinal tract. Studies of stools after the ingestion of uncooked starchy foods showed that the digestion of starch was complete. The time of digestion, however, was decidedly prolonged.

For this test to have validity, well-cooked starch should be used. Thus, in another study (Wishnofsky and Kane, *Am. J. M. Sc.* 189:545-550 [April] 1935), the starchy food given was thoroughly cooked or baked and consisted of 150 Gm. of potato and 30 Gm. each of barley, rice, and bread (toast), which contained, respectively, 30.0, 22.4, 22.4, and 15.0 Gm. of carbohydrate. Incidentally, in the 20 diabetic patients studied, the glycemia and glycosuria after the ingestion of 90 Gm. of starch and 100 Gm. of dextrose were identical.

The authors were in error in using 100 Gm. of dextrose and 100 Gm. of starch because, from the standpoint of carbohydrate value, these amounts are not equivalent. The elementary formula for starch is $(C_6H_{10}O_5)_n$ with a molecular weight of n (162). The molecular weight of dextrose $(C_6H_{12}O_6)$ is 180. The complete hydrolysis of 90 Gm. of starch yields 100 Gm. of dextrose.

MAX WISHNOFSKY, M.D.
615 Williams Ave.
Brooklyn 7, N. Y.
ARTHUR P. KANE, M.D.
1801 Gerritsen Ave.
Brooklyn, N. Y.

To the Editor:—The comments of Dr. Wishnofsky on the article by Dr. Millhon and myself are of interest. This test was originated and standardized by Dr. Althausen and his associates. Their original report excited much enthusiasm for this test as a diagnostic aid in pancreatic disease. Dr. Millhon and I merely published our experience with the test because we were unable to duplicate the results reported by the original authors. We do not claim that this is a satisfactory test of pancreatic function. The basis of the test is that intestinal amylase must be present to break down starch, a polysaccharide, so that it may be absorbed in the form of disaccharides or monosaccharides from the intestinal tract. Therefore, the suggestion of Dr. Wishnofsky that we use well-cooked starch is not valid. Well-cooked starch is already reduced, to a great extent, and therefore would not depend on the presence of amylase for its absorption.

NEW YORK INDIGENT MEDICAL CARE PROGRAM

To the Editor:—In the interesting department of The Journal, Medicine at Work, Jan. 10, 1959, pages 143-151, the material on nursing homes implied that an indigent medical care program was not available in New York state. New York state has one of the oldest and most adequate systems of medical care for the needy and the medically indigent in the United States. Any person who requires medical care but cannot pay for it may receive that care as a public charge. It is provided through the medical-care services of the local public welfare department and through the hospital-care program of the local community.

The local public welfare program provides medical, surgical, dental, nursing, hospital, laboratory, x-ray, radium, physiotherapy, and allied services, including medicaments and prosthetic appliances, for all persons on the public welfare rolls who require such care and for medically indigent persons as well. There is no limitation as to type, kind, or amount of medical care which an eligible person may receive. It is granted by the local welfare departments as needed, on advice of a physician. It may be provided in a physician's office, the patient's home, a hospital, a nursing home, or in other facilities. Local welfare departments provide these services primarily by purchasing them from local physicians, surgeons, and other medical personnel and from local facilities such as hospitals, dispensaries, specialized medical institutions, and nursing homes.

A monthly average of about 500,000 men, women, and children on the public assistance rolls receive medical care as needed, as do 40,000 children in foster-family homes and child-care institutions and 5,000 aged men and women in public homes. State, local, and federal funds pay for this medical care. In addition, a monthly average of 50,000 medical indigents have their hospital and dispensary bills paid by their local communities. In 1957 about $200,000,000 was spent for the medical care of welfare recipients and the medically indigent by public welfare agencies in New York state.

MEDICOLEGAL ABSTRACTS

Malpractice: Testimony by Witnesses of Different Schools of Practice Than That of Defendants.—This was an action for damages for injuries resulting from the alleged negligent conduct of the defendant osteopathic surgeons. From a judgment in the trial court in favor of the plaintiff, the defendants appealed to the court of civil appeals of Texas.

Following the performance of a total hysterectomy by the defendant osteopathic surgeons, the plaintiff failed to void urine for 48 hours. Then she started to urinate uncontrollably through the vagina rather than the urethra. This condition continued after she was dismissed from the defendants' clinic. She eventually went to Baylor Hospital and underwent corrective surgery for the repair of a vesicovaginal fistula, the surgeons being members of the allopathic rather than the osteopathic school of medicine.

It was the contention of the defendants that the plaintiff had not established proof of their negligence by doctors of the same school of medicine as they practiced. The plaintiff's witnesses were the allopathic surgeons who performed the later corrective surgery at Baylor Hospital.

In an earlier decision of the Supreme Court of Texas, the court said, "It is definitely settled with us that a patient has no cause of action against his doctor for malpractice, either in diagnosis or recognized treatment, unless he proves by a doctor of the same school of practice as the defendant (1) that the diagnosis or treatment complained of was such as to constitute negligence, and (2) that it was a proximate cause of the patient's injuries." A limitation of this general rule was stated in a later case, however, to the effect that testimony of physicians of a different school is competent (1) where the subject of inquiry is common to and equally recognized in all fields of practice; or (2) relates to the manner and use of electrical or mechanical appliances commonly used in all fields of practice.

The evidence in this case indicated that the methods, training, and dangers incident to the operation in question are common to both schools of medical practice and equally recognized. The evidence also showed that the acts and omissions proved in the case would amount to negligence in any locality and that no surgeon of any school should leave a patient, after a hysterectomy, with blocked ureters and fistulas in both bladder and vagina.

The judgment in favor of the plaintiff was therefore affirmed. *Miles v. Meadows,* 309 S. W. (2) 284 (Texas, 1958).

MEDICAL FILM REVIEWS

Correction of Micrognathia: 16 mm., color, sound, showing time 12 minutes. Prepared by James W. Kelley, M. D., Tulsa, Okla. Produced in 1958 by Bud Woods Productions, Tulsa. Procurable on loan from James W. Kelley, M.D., 204 Utica Square, Tulsa.

This is a good film on one method of treatment of an infant with severe micrognathia. The approach is fairly new: the tongue is sewn to the lower lip to keep the tongue from falling back during the critical period of early infancy. After a few months the tongue can be freed with no apparent damage. The photography and sound are very good and the techniques used are all clearly illustrated. This film is recommended for oral surgeons, pediatricians, general practitioners, and medical students.

The Larynx and Voice: Physiology of the Larynx Under Daily Stress: 16 mm., color, sound, showing time 23 minutes. Sponsored by the William and Harriet Gould Foundation. Prepared in 1958 by and procurable on rental or purchase ($100) from Hans von Leden, M.D., 30 N. Michigan Ave., Chicago.

This is the second in a series of films on the larynx and voice. It demonstrates the complex pattern of laryngeal function during everyday life and presumes a knowledge of the fundamental anatomy and physiology of the larynx which was described in the first film entitled "Function of the Normal Larynx." This film goes into somewhat more detail. The photographic equipment and technique are shown in greater detail, and many high-speed pictures of the larynx in action have been included. In addition, there is a discussion of the physics of laryngeal activity and how the laryngeal tone may be produced and modified. This film would make a good addition to an undergraduate college course in biology, a graduate course in anatomy and physiology of the vocal mechanism, and anatomy courses given to medical students. There is sufficient detail and information to provoke further interest and to provide the student with a working knowledge of the laryngeal structure.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

You and Your Eyes: 16 mm., color, sound, showing time 8 minutes. Produced in 1956 by Walt Disney Productions, Burbank, Calif. Procurable on loan (service charge $1.50) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film discusses the eye—how it works and how the function of seeing takes place. Jiminy Cricket introduces the subject by pointing out how highly developed is man's sense of seeing compared to his other senses, and how his inventions of telescope and microscope have extended his capabilities. He also sets down some safety rules for proper care of the eyes. This is an extremely attractive film. It is clever, colorful, and amusing and is well suited for showing to children at the kindergarten and lower elementary grade level.

You Are There: The First Major Use of Penicillin: 16 mm., black and white, sound, showing time 25 minutes. Produced in 1955 for a CBS television program. Procurable on loan (service charge $2.00) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film pictures the events of one week in 1943 when penicillin, still an unknown quantity in medicine, was being tried on a group of patients with chronically infected wounds sustained in the Pacific theater of World War II. After introductory remarks by Walter Cronkite there is a succession of scenes in the Army hospital where the clinical trial took place, in the laboratories of Fleming and Florey in England, the office of Dr. Chester Keefer in Washington, the laboratory of Jasper Kane at Chas. Pfizer Inc., and finally the hospital once again. The film succeeds in giving an audience some appreciation of the dilemmas of patients, doctors, and manufacturers when confronted with a new pharmaceutical preparation. The film is scientifically accurate. Suspense and interest are sustained throughout. It would be best suited for mature nonprofessional audiences and should also be of interest to medical students.

Hormonal Cyto-Diagnosis: Vaginal Smears: 16 mm., color, sound, showing time 21 minutes. Prepared in 1955 by Prof. André Sicard, Faculty of Medicine, Paris. Sponsored by Ciba Limited, Basel, Switzerland. Procurable on loan (service charge $2.00) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film discusses the value of vaginal smears for studying the ovarian cycle, diagnosing functional disorders therein, and applying appropriate treatment. The technique of cytodiagnosis involved is depicted in detail, and the various elements encountered in vaginal smears are described and interpreted. The film also deals with tubal insufflation, hysterosalpingography, and the early diagnosis of pregnancy. This film contains some magnificent photomicrography, and the color photography is excellent. The entire menstrual cycle is reviewed and the various types of cells normally seen in a vaginal smear are demonstrated. This picture represents a magnificent lesson in human vaginal cytology. It is recommended for physicians, cytologists, and possibly for medical students.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Differing Mechanisms of Action of Mercurials, Carbonic Anhydrase Inhibitors, and Chlorothiazide as Diuretic Agents. R. V. Ford and J. B. Rochelle. J. Lab. & Clin. Med. 53:53-63 (Jan.) 1959 [St. Louis].

The authors studied the effects of 3 diuretic agents, given alone or in various combinations, namely, meralluride (Mercuhydrin) sodium, acetazolamide (Diamox), and chlorothiazide (Diuril), on the excretion of sodium and other electrolytes, such as potassium, chloride, and bicarbonate, in the urine of patients with well-controlled chronic congestive heart failure due to hypertensive cardiovascular disease. Beginning at 7 a. m. and throughout the study, isotonic sodium chloride solution was infused intravenously at a rate of about 650 microequivalents of sodium per minute to prevent depletion of body stores of sodium, which might be reflected in decreased urinary sodium, especially after potent diuretic administration. Contemporary observations of glomerular filtration rate (inulin clearance) and renal plasma flow (*p*-aminohippurate clearance) were made.

The primary action of the diuretic agents studied is the augmentation of the renal excretion of sodium. The results of the study suggested that the mechanisms of action of meralluride sodium and acetazolamide are noncompetitive and different, i. e., different "receptor sites" are acted upon or different renal transport mechanisms for the reabsorption of sodium are inhibited. The mechanism of action of meralluride sodium is competitive with that of chlorothiazide; these 2 agents share a single mechanism of action or receptor site (for transport inhibition), but chlorothiazide can "block" the effect of subsequent doses of meralluride sodium, while meralluride sodium cannot "block" the effect of subsequent doses of chlorothiazide on the excretion of sodium. In a similar way the mechanism of action of acetazolamide is competitive with that of chlorothiazide; these 2 drugs share one mechanism of action or receptor site, and yet chlorothiazide apparently can act through another mechanism which is noncompetitive with acetazolamide.

The third mechanism of action as a diuretic exemplified by chlorothiazide cannot be inhibited by the concurrent administration of meralluride sodium and acetazolamide, i. e., the receptor site (for the inhibition of renal reabsorption of sodium) of chlorothiazide cannot be "saturated" by meralluride sodium or acetazolamide. This additional mechanism of action of chlorothiazide may imply involvement of another enzyme system, or it may imply a greater range of activity of chlorothiazide throughout the nephron. Contemporary observations of renal hemodynamics (glomerular filtration rate and renal plasma flow) did not reveal any significant changes.

Atrial Fibrillation and Its Treatment: Observation of 100 Patients. B. Migheli. Omnia therap. 9:225-267 (April-June) 1958 (In Italian) [Pisa, Italy].

One hundred patients with atrial fibrillation, 54 of whom had previously received digitalis, were placed on quinidine therapy. The mitral valve was affected in 63 patients, and myocardial sclerosis was present in 37. Forty-eight patients had cardiac decompensation. The total dosage of quinidine varied between 3.4 and 22.6 Gm. Patients received 200 mg. of the drug on the first day and 400 mg. on the second day, the dosage being gradually increased each day so that from 200 to 600 mg. was added to that of the preceding day. The daily dosage was divided into several doses, with an interval of at least 3 hours between doses. Sinus rhythm was restored in 78 patients (78%).

Better results were obtained with quinidine in patients (*a*) who had not previously received digitalis, (*b*) who had a defective mitral valve rather than myocardial sclerosis, (*c*) who had cardiac compensation rather than cardiac decompensation, and (*d*) who were in the age brackets from 20 to 40 years and from 61 to 70 rather than in the age brackets from 41 to 60 years and from 71 to 80. There was no apparent difference in therapeutic results between the sexes. Of 32 failures, 2 patients died during the administration of quinidine, although death was apparently unrelated to the therapy; the drug was withdrawn from 20 patients before completing the planned regimen. Toxic reactions, which did not induce discontinuance of the therapy, developed in 9 patients, and embolism was observed in 1. Disturbance of the ventricular neu-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

romuscular conduction mechanism was the main toxic effect which induced withdrawal of quinidine from 13 patients. Since this disorder cannot be detected by ordinary clinical means, one or two daily inspections of cardiograms are recommended. Hypotension, vomiting, nausea, vertigo, atrial murmurs, and diarrhea were noted in 13 patients, which induced withdrawal of the drug from 6. Recurrence of atrial fibrillation during hospitalization was observed in 13 instances (12.8%). Quinidine was an efficacious drug for the management of atrial fibrillation in this series of patients. The initial administration should be complemented by complete bed rest, and the patient should be put on a permanent maintenance therapy afterwards.

Gastroscopy. M. Sundberg. Finska läk.-sällsk. handl. 101:38-47 (no. 1) 1958 (In Swedish) [Helsinki].

Sundberg compares the roentgenologic and gastroscopic findings in 71 patients, in whom the final diagnosis was established at operation or autopsy, and analyzes gastric processes—ulcer, carcinoma, polyposis. The roentgenologic diagnosis was correct in 21 of the 29 cases of ulcer, and the gastroscopic, in 16 cases. The roentgenologic diagnosis was correct in 15 of the 28 cases of carcinoma, and the gastroscopic, in 21. Roentgenologic examination gave correct results in 3 of 5 cases of polyposis, and the gastroscopic diagnosis, in 4 cases. In the 9 additional cases in which operation revealed no pathological process in the stomach, the gastroscopic diagnosis was correct, while the roentgenologic examination gave conclusive results in only 2 cases. Four cases of carcinoma were detected only by gastroscopy, and in 5 additional cases, 2 of carcinoma and 3 of ulcer, gastroscopy confirmed uncertain roentgenologic results. Gastroscopy cannot be a substitute for roentgenologic examination but is a valuable supplementary method.

Familial Hypercholesteremic Xanthomatosis: A Preliminary Report. I. Clinical, Electrocardiographic and Laboratory Considerations. J. L. Guravich. Am. J. Med. 26:8-29 (Jan.) 1959 [New York].

In an attempt to correlate the serum lipid and lipoprotein determinations with the clinical and electrocardiographic findings in 2 families with the hypercholesteremic trait, the author studied 103 persons, 99 of whom belonged to one family (designated kindred 1) and 4 to the other family (designated kindred 2). Thirty-eight persons in kindred 1 and 3 persons in kindred 2 were found to have hypercholesteremia. These included 3 who were spouses. Twenty-five persons had serum cholesterol values in what has been designated a "borderline" zone, i. e., from 250 to 300 mg. per 100 cc. Thirty-seven persons had normal cholesterol concentrations. It is suggested that some of those whose serum cholesterol values were in the "borderline" zone might actually be hypercholesteremic. Some persons were stable and others were labile with respect to their serum cholesterol values. Thus, single estimations are not always to be relied on as a basis for determining normalcy or abnormalcy. In all 41 persons with hypercholesteremia, the S_f 0-12 lipoprotein values were elevated; the S_f 12-20 lipoprotein values were elevated in most of these persons; in slightly more than half of the persons in whom the results of lipoprotein determination were available, there was an elevation of the S_f 20-100 fractions, while the S_f 100-400 lipoprotei values were normal in most instances. The lipoprotein values were normal or near normal in th "borderline" persons and in persons with a norma cholesterol serum level.

Tendon, fascial, or periosteal xanthomas occurre in 23 of the 41 patients with hypercholesteremia They did not occur in any of the spouses. In addition to the commonly described sites of origin some xanthomas were observed originating in site not previously described: the plantar aponeurosis periosteum overlying the lower tibia and media malleoli, and the peroneal and posterior tibia tendons. Cutaneous xanthomas (excluding xanthelasmas) occurred in 2 patients. Xanthelasmas wer observed in 6 patients. Although the incidence o xanthomas increased with increasing age, the relationship was not absolute, some patients wit hypercholesteremia having reached the 6th and 7t decades without the development of xanthomatosi Some correlation between xanthomatosis and th degree of hypercholesteremia was observed, bu here again there were exceptions. No xanthoma were found in persons with normal serum cholesterol levels or in "borderline" persons. Arcus senili occurred in 22 patients with hypercholesteremi 11 of whom were less than 50 years of age. Only persons with normal serum cholesterol levels an 2 "borderline" persons had arcus senilis.

Fourteen patients with hypercholesteremia ha clinical coronary artery disease. Four of these die of coronary occlusion in the course of the author study. All had electrocardiographic abnormalitie either in the electrocardiograms taken at rest o after the two-step test. In 16 asymptomatic patien with hypercholesteremia, the Master two-step te was carried out; the response to exercise was abnormal in 9. It is suggested that, in some of thes patients, this test might indicate "occult" or presymptomatic coronary artery disease. Anginal pai was not present in the "borderline" group, but ther was electrocardiographic evidence of an old posterior infarct in one patient. Of 16 two-step test 5 were positive. In the group of persons with no mal serum cholesterol levels, one patient had def nite clinical coronary artery disease (an ol posterior infarct), and 2 were suspected of havin angina pectoris. One of the latter had a positiv two-step test. Two of 10 asymptomatic patien with normal serum cholesterol level who underwent this procedure had positive two-step tests. The incidence of hypertension and cerebrovascular and peripheral vascular disease in this series was low. It is suggested that hypertension and diabetes are more likely to be associated with these forms of atheromatous disease than is hypercholesteremia per se. Age too is an important factor; all but one of the patients who had clinical evidence of aortic or peripheral arterial disease or who showed calcification of pelvic or lower limb arteries on x-ray examination were in the 6th or the 7th decade. These data again point up the pathogenetic relationships between hyperlipidemia and the clinical manifestations of xanthomatosis and atherosclerosis. Taking into account the factors of age and sex, there was a general, although by no means absolute, correlation between blood lipid levels and the development of xanthomas and coronary artery disease, overt or subclinical.

The Incidence of Gall Stones. J. R. Cain and H. Donato. J. South Carolina M. A. 55:17-19 (Jan.) 1959 [Florence].

The authors investigated the relative incidence of gallstones with regard to sex, age, and race. Their report is based on 6,107 autopsies performed at the Medical College of South Carolina and the Roper Hospital in Charleston during 1913-1948. In order to ascertain whether improvement in diet might be accompanied by an increase in the incidence of gallstones, the autopsy records were divided into 2 groups, depending on whether the autopsies were performed before or after 1939. It was felt that the increased incidence should be more apparent in the Negro race, since Negroes had probably made proportionately greater strides in recent years in enhancing their diet.

The authors found that the white race is approximately 3 times more susceptible to gallstones than the Negro race. Equally striking is the consistent sex difference, with females having a significantly higher incidence than males and with white females having the highest incidence. The incidence of gallstones rises with age; they are rare in children. Whether the slight increase in incidence of gallstones during 1940-1948, over 1913-1939, is significant cannot be determined.

Studies of the Influence of Comfortable and Hot and Humid Environments Upon the Rate of Excretion of H^3, H_2O, Cl^{36}, Cl^{35}, Na^{23}, Rb^{86}, and K^{39} in Control Subjects and Patients with Congestive Heart Failure. G. E. Burch and C. T. Ray. J. Lab. & Clin. Med. 53:89-105 (Jan.) 1959 [St. Louis].

The authors studied the influence of a hot and humid hospital environment during the summer on certain phases of electrolyte and water metabolism in 9 women, between the ages of 22 and 65 years; 5 of these patients had chronic congestive heart failure, and the other 4 (1 convalescent from a respiratory infection, 1 with tuberculous arthritis, 1 with sarcoidosis, and 1 convalescent from a lung abscess) served for contratests. These 9 patients were studied in 2 wards of the Charity Hospital of Louisiana in New Orleans; one ward was air-conditioned, and the environment of the other ward was hot and humid. The patients spent about equal time (2 weeks) in both environments. Three of the patients with chronic congestive heart failure and 2 of the contratest patients were given intravenously radiochloride (Cl^{36}), radiorubidium (Rb^{86}), and tritium hydroxide (H^3OH) simultaneously at the onset of the studies. Dietary intake of sodium, chloride, potassium, and water was recorded, and the urinary excretion of these substances was measured. Urinary clearance rates were determined for Cl^{36} and Rb^{86} as well as stable chloride, stable sodium, stable potassium, and tritium (radiohydrogen, H^3). Osmolar excretion, glomerular filtration rate, and renal tubular reabsorption were measured.

The results showed that a hot and humid summer environment produced in most of the patients a significant increase in extrarenal losses of water and electrolytes, even though the patients were at bed rest. In addition, there was an increase in osmolarity of the urine, with a tendency to negative-free water clearance. An unusual voluntary intake of water developed in some of the patients acclimatized to a hot and humid summer and continued while they were in the air-conditioned ward where extra requirements for water were not necessary. The habit of drinking large quantities of water appeared to be a manifestation of acclimatizing adjustments made by some people of Louisiana to the heat and humidity of summer. Probably with a longer period of residence in the cool environment the intake would have declined to the usual levels. The high intake, although adequate for the hot and humid environment and assuring essentially an average normal urinary state, resulted in a diluted urine of large volume when continued in the cool environment.

The experiments revealed marked daily fluctuations in urinary clearance and excretion of Cl^{36}, Rb^{86}, stable chloride, stable sodium, stable potassium, tritium, and water, when intake of these substances and physical activities were relatively constant. In view of these variations it is necessary to exercise caution when observing renal function and urinary excretion with only a few such measurements. The daily endogenous creatinine clearances recorded for 26 consecutive days revealed no significant differences between time course and magnitude of rate of glomerular creatinine clearance of the patients with or without chronic congestive heart failure. The patients with heart failure had both remission and exacerbations in their failure during the observation period. It was evident that any variations in renal function associated with the congestive heart failure were primarily tubular. It would likewise appear that, unless congestive failure is severe, glomerular filtration remains within normal limits, at least for patients with moderately severe chronic congestive heart failure.

Although only 3 radioactive isotopes were employed in this study, it revealed the facility with which renal function may be followed continuously and simultaneously with different radioactive isotopes. A larger number of such isotopes could be used equally well by taking advantage of differences in rates of physical decay and energy and spectrums of radiation. By adding support to the physiological data previously described in man, with and without chronic heart failure, for Cl^{36}, Rb^{86}, stable chloride, stable sodium, and stable potassium and by adding the simultaneously observed renal excretion of H^3OH, the authors' study increased the validity of the findings for man as a whole.

Primary Diffuse Interstitial Pulmonary Fibrosis (Hamman-Rich) Syndrome. E. Hansen. Nord. med. 60:1710-1715 (Nov. 27) 1958 (In Danish) [Stockholm].

The Hamman-Rich syndrome is a diffuse, progressive, interstitial fibrosis of the lungs of unknown etiology, ending in death after a few years and in especially fulminant cases within a few months. The pathological picture presents characteristic and marked changes. In clinically and roentgenologically suspected cases, diagnosis can be decided only by taking a lung specimen for biopsy. Hamman and Rich emphasize that the syndrome is distinguished from the carnification process after an unresorbed croupous pneumonia in that there is only a slight tendency to organization of the intra-alveolar exudate and that the growth of connective tissue into the alveoli seen in carnification is lacking. The main symptoms are cough, with as a rule no, or only scanty, viscous expectorate, dyspnea that develops gradually, and increasing cyanosis. The roentgenologic findings, as a rule, leave no doubt as to a pulmonary disease but are so atypical that the diagnostic possibilities are numerous. The disease is primary in the sense that it cannot be ascribed to any preceding pulmonary disease, but a relation to earlier virus pneumonias cannot be excluded. Recent experiences seem to show that steroid treatment can at least temporarily stop or retard the fibrosing, but renewed progression after ended treatment indicates that the unknown stimulus continues to be active and the effect of the steroid treatment is only a suppression of the organism's reaction to this stimulus. The latest report on the effect of cortisone treatment over a longer period apparently permits a certain therapeutic optimism. The effects of corticotropin and cortisone make these drugs useful in the treatment of relatively new and rapidly progressive cases and improve the hitherto bad prognosis.

Agammaglobulinemia and Respiratory Infection. J. Bouton, E. Fogel Korc, I. Korc and others. Tórax 7:89-118 (June) 1958 (In Spanish) [Montevideo, Uruguay].

A deficiency or absence of gamma globulin in the blood, either idiopathic or occurring secondarily to diseases of the lymph nodes or of the reticuloendothelial system, is rare. The main features characterizing agammaglobulinemia are: (1) multiple infections, especially respiratory infection; (2) absence of antibodies and isoagglutinins; and (3) absence of serum gamma globulin in the electrophoretic proteinogram, whereas the other fractions are normal. The condition may be treated by the periodic administration of intramuscular injections of purified gamma globulin (human) so as to prevent recurrences of the infections. Respiratory infection, as a rule, occurs in association with gastrointestinal and other infections and is often complicated by fatal suppurative meningitis. There is neither acquired nor induced immunity, as evidenced by a negative tuberculin reaction and by positive Dick and Schick reactions. Sputum cultures during bouts of respiratory infection have revealed Diplococcus pneumoniae as the predominant organism. Both in the acute and in the chronic phases of the disease, the sputum is negative for tubercle bacilli.

The authors report the case of a 17-year-old girl, who was hospitalized in the Pablo Purriel Hospital of Montevideo during an episode of respiratory infection, from which she had suffered since the age of 3 years. Bilateral bronchiectasis had been observed at the age of 6, and splenomegaly and symptoms of hypersplenism at the age of 10. These symptoms paralleled the recurrent respiratory infection and regressed with remission of the disease. A brother who had also suffered from recurrent respiratory disease since birth died at the age of 10 months of bronchopneumonia complicated by meningitis. The electrophoretic proteinograms of the parents and of 3 sisters were normal, but those of 2 brothers showed hypogammaglobulinemia. The grandparents of all these siblings were first cousins. The patient, on hospitalization, had anemia as well as agammaglobulinemia, and a sternal myelogram showed changes of granulocytic hyperplasia. Treatment consisted of the intramuscular injection of a 12% solution of purified gamma globulin (human) in a dosage of 0.15 cc. per kilogram of body weight. Tetracycline and nystatin were also given but only during the period of acute infection. Gamma globulin continued to be administered in individual doses and at intervals which were adjusted according to the ratio of serum gamma globulin in the periodically controlled proteinograms. With this maintenance therapy the patient's bronchopulmonary symptoms and diarrhea subsided, splenomegaly was greatly diminished, anemia disappeared, and leukocytosis became normal. The respiratory and other infections have not recurred, and the ratio of serum gamma globulin in the proteinogram stands at 11%.

According to the authors, antibiotics should be administered to patients with agammaglobulinemia only during the period of acute infection. Prolonged or untimely administration may cause resistance of the intestinal bacteria, with consequent chronic intestinal infection. Blood transfusion and the administration of hormones and vaccines, including BCG, are interdicted. Blood transfusion may be followed by a fatal viral hepatitis, and hormones and vaccines are unnecessary, and even dangerous, because of the immunological defects of the patients.

Palpability of the Liver Edge in Healthy Adults. E. D. Palmer. U. S. Armed Forces M. J. 9:1685-1690 (Dec.) 1958 [Washington, D. C.].

Uncertainty over just how far below the costal margin the right lobe of the adult liver may normally extend seems to be common. The location of the lower edge of the liver does not necessarily bear a relationship to the size of the organ, and one must determine the position of the liver's cephalad limit by percussion before hepatomegaly can be diagnosed. Nevertheless, diffuse hepatomegaly manifests itself almost wholly in the downward direction. Conversely, any great degree of extension of the liver's edge below the costal margin almost always indicates hepatomegaly. The studies described were concerned with the range of positions occupied by the inferior border of the liver's right lobe, as judged by palpation, in a group of normal adults. Observations on the liver were recorded during routine physical examinations on 1,000 military subjects who were free from liver disease.

The author shows that it is necessary to be very precise about the point at which the measurement is made when recording liver size on the basis of the position of its edge. The best point for the determination lies along a line just lateral to the right rectus muscle margin, in the linea semilunaris. The liver edge in 42.6% of the subjects could not be palpated, and in 14.4% it could be felt to descend to the costal margin but not beyond; in 15% it descended 1 cm. below the costal margin; in 12.9% it descended 2 cm.; in 8.2%, 3 cm.; in 5.7%, 4 cm.; and in 1.2%, 5 cm. No correlations could be found between the position of the liver's edge and the subjects' sex, age, height, weight, or subcostal configuation. In commenting on these findings, the author points out that the examinations were made at various times throughout the day. The normal adult liver, which weighs about 1,500 Gm., contains about 800 ml. of blood. The blood content, therefore, exerts an important influence over liver weight and size. Because, presumably, this blood fluctuates with the phase of digestion and physical activity, it must be supposed that liver size may vary significantly from hour to hour during the day and perhaps from day to day.

Experiences with the Artificial Kidney at the Medical College Hospital. C. M. Smythe, A. V. Williams and J. Buse. J. South Carolina M. A. 55:5-9 (Jan.) 1959 [Florence].

The authors summarize experience gained with extracorporeal dialysis in the treatment of patients with acute renal failure at the Medical College Hospital in Charleston. They used the Kolff type of disposable dialyzing unit for 16 dialyzation treatments in 11 patients chosen from a large group with acute and chronic renal failure. On the basis of a detailed case report, the authors show that during the development of hyperkalemia or uremia dialysis will have to be repeated at frequent intervals. In general, timing of dialysis and careful attention to fluid and electrolyte balances and to electrocardiographic changes proved important.

Diagnosis has remained a major problem. Not only has it been difficult to judge the exact etiological agent causing acute anuria but even whether a patient has acute renal disease. Acute renal failure after acute trauma is simple enough to diagnose. However, in postpartum patients the differential diagnosis between tubular and glomerular injury may be difficult. This is of vital importance, for severe glomerular destruction is essentially irreversible. Difficulties arise also in patients with medical problems. Thorough history taking is important to establish the presence or absence of preexisting renal disease. Eyeground changes, heart size, cardiac contour, and electrocardiographic changes may help in differentiating an exacerbation of chronic renal disease from acute renal disease.

The authors found the dialyzing apparatus to be serviceable and practical. Six of the 11 patients survived. Four of these had acute renal failure, and all 4 are well at present. Three of the 5 patients who died were examined at autopsy and were found to have irreversible kidney disease.

Corticotrophin and Steroids in the Diagnosis and Management of "Obstructive" Jaundice. W. H. J. Summerskill and F. A. Jones. Brit. M. J. 2:1499-1502 (Dec. 20) 1958 [London].

In 12 patients with obstructive jaundice of uncertain cause, the effect of a 5-day trial of steroid or corticotropin therapy was of great value in reducing serum bilirubin levels and in differentiating between intrahepatic obstruction due to hepatitis and extrahepatic obstruction. Serum alkaline phosphatase concentrations also fell during treatment, although to a less extent, thus suggesting that the reduction of jaundice caused by corticotropin or steroid drugs was due to increased bile excretion. The drugs acted immediately, and no difference was apparent between corticotropin and steroids.

These findings accord with earlier observations that corticotropin and steroid compounds may influence the jaundice both of hepatitis and of extrahepatic obstruction, but they challenge the conclusion that the drugs have no value in the differential diagnosis between the 2 conditions. Four of 5 patients with intrahepatic obstructive jaundice due to hepatitis had reductions in serum bilirubin levels which exceeded any that occurred in patients with extrahepatic obstruction due to tumor. The "critical" figure in this series was a fall in the serum bilirubin level of 8% or more a day in a period of 4 to 8 days, and review of earlier studies in patients with extrahepatic biliary obstruction shows that such a response to corticotropin is rare. The continued administration of the drugs to those who have shown a response to the initial test permits a confident diagnosis of hepatitis, if there is sustained improvement. Corticotropin or steroid therapy is the treatment of choice for such patients. Failure to improve with treatment does not exclude hepatitis. In viral hepatitis, a proportion of patients may present with variable clinical, biochemical, or histological features of obstruction. Six patients with such cholangiolitic findings responded to corticotropin much better than many other patients with hepatitis.

SURGERY

Spontaneous Hematoma of the Rectal Abdominal Muscles: A Clinical Contribution. A. Pannella. Riforma med. 72:1303-1308 (Nov. 15) 1958 (In Italian) [Naples].

Three patients, 2 female and 1 male, aged 70, 78, and 74 years, respectively, with spontaneous hematoma of the rectal abdominal muscles are reported on. The symptoms appeared suddenly in all the patients, the condition having been caused by spells of coughing. Swelling occurred on the left side of the epigastric region in one patient and to the right of the mesogastric region in the other two. The surface of the swelling was smooth in the first and second patients, the skin covering the swelling having an ecchymotic color in the first patient and a color which was between dark blue and yellowish green in the second. There was also an ecchymotic discoloration of the skin swelling in the third patient. In all the patients this swelling, after having appeared suddenly, regressed gradually within a short period of time. No intestinal disturbances or peritoneal symptoms were present, but all the patients had arteriosclerosis. The first and third pa tients were subjected to medical therapy and the second to surgical therapy, with good results.

On Surgically Treated Herniated Intervertebra Discs. B. Knutson and G. Wiberg. Acta orthop scandinav. 28:108-123 (no. 2) 1958 (In English [Copenhagen].

The authors report on 134 men and 117 womer between the ages of 16 and 68 years, who wer operated on for protruded or herniated interverte bral disk in the department of othopedic surger of the University Hospital of Lund, Sweden. Weak ness in dorsal flexion of the great toe was noted i 58 (71%) of 82 patients, in whom the power of thi dorsal flexion was tested and in whom surgic intervention revealed protrusion or prolapse of th disk at the 4th and 5th lumbar vertebrae levels. C those patients on whom paresis of the great toe wa observed, surgical intervention revealed protrusio or prolapse of the disk between the 4th and 5t lumbar vertebrae in 63%. Of the 133 patients i whom surgical intervention revealed prolapse the disk between the 5th lumbar and 1st sacr vertebrae, the achilles tendon reflex was impaire or absent in 111 (83%). Of those patients in whor clinical examination revealed impairment or al sence of the achilles tendon reflex, surgical inte vention revealed protrusion or prolapse of the dis between the 5th lumbar and 1st sacral vertebra in 81%.

Myelography was performed with the aid of ai oxygen in 80 patients and with the aid of a wate soluble Scandinavian contrast medium preparatio in 63 patients. Of those in whom myelograph showed a protrusion between the 4th and 5th lun bar vertebrae, surgical intervention confirmed tl finding in 77% of those from whom myelogran were obtained with air-oxygen, and in 93% of tho from whom myelograms were obtained with tl aid of the contrast medium. Surgical interventic revealed protrusion or prolapse of the disk betwee the 4th and 5th lumbar vertebrae in 36% and pr trusion or prolapse of the disk between the 5 lumbar and 1st sacral vertebrae in 69% of tho patients in whom myelography with air–oxyge had shown no signs of an abnormal condition. Su gical intervention revealed protrusion or prolap of the disk between the 4th and 5th lumbar vert brae in 1 patient, and between the 5th lumbar an 1st sacral vertebrae in 9 of 12 patients whose myel grams obtained with the aid of the contrast mediu did not show any signs of an abnormal conditio Myelography with the aid of a water-soluble co trast medium gives more reliable results than my lography with the aid of air–oxygen, but a certa degree of roentgenologic overdiagnosis and unde diagnosis must be expected.

A questionnaire was mailed to the 251 patients within 4 to 12 years after the surgical intervention, and 241 (96%) replied. Improvement was reported by 228 (94.5%), and the remaining 13 patients (5.5%) reported no change or deterioration. The time required for postoperative recovery varied from 6 weeks to 1 year.

Surgical Treatment of Stenosis of the Aqueduct of Sylvius: Considerations on 75 Patients Operated On. I. Papo and R. Tritapepe. Minerva chir. 13: 1299-1305 (Nov. 30) 1958 (In Italian) [Turin, Italy].

The authors report on 75 patients with hydrocephalus caused by stenosis of the aqueduct of Sylvius, who were operated on during the period from 1938 to 1957 in the surgery clinic of the University of Milan. Sixty-two patients were below 30 years of age. One of 2 patients subjected to decompression of the posterior cerebral fossa was dismissed from the hospital in fair condition but was lost sight of; the other patient was still alive and working 13 years after the operation. One patient subjected to removal of the obstruction died of purulent meningitis.

Twelve of the 62 patients subjected to ventriculocisternostomy, according to the Stookey-Scarff technique, died while still in the hospital. Ten of these patients derived no benefit from the operation and showed no improvement. Immediate onset of increasing coma followed in 8 patients who later suffered marked hyperthermia and decerebrate rigidity. One patient during the operation, carried out under local anesthesia, suffered general epilepsy with cerebral edema, which caused death after a few hours. One patient soon after the operation developed intense bronchorrhea, with respiratory disturbance and cardiocirculatory insufficiency, and died 5 days later. Two patients who died in hyperthermic coma, with severe cerebrospinal hypertension, at preoperative cisternography presented a blocking at the level of the cisternae basales. Two patients, after deriving some benefit from the operation for a period of 9 and 5 days, respectively, suffered a relapse of the intracranial hypertension, which became progressively worse and was accompanied by sopor; hyperthermic coma and decerebrate rigidity developed later. These patients died 12 and 30 days, respectively, after the operation.

The Stookey-Scarff ventriculocisternostomy was not sufficient in 12 patients to check permanently the intracranial hypertension. Seven of these patients eventually were subjected to other procedures. Of the 5 patients who were not reoperated on, 2 showed postmeningeal blocking, with obstruction of the cisternae basales, and derived no benefit from the operation; one of them died after 2 months. A third patient showed no clear remission of the symptoms of hypertension and was readmitted to the hospital after 7 years, with dementia, severe reduction of vision, and astasia-abasia. In the remaining 2 patients relapse of hypertension occurred a few months after the operation, and one of them died within 4 months. Ventriculocisternostomy according to the Stookey-Scarff technique, however, had a beneficial effect on 34 patients, in whom a good equilibrium was obtained, and the intracranial hypertension disappeared. Twelve of these patients were lost sight of, but 22 are still alive and in good condition from 14 months to 15 years after the operation.

Some patients who derived no benefit from the Stookey-Scarff operation were later subjected to the Torkildsen operation but with no success. In addition, the Torkildsen ventriculocisternostomy was performed, as the first operation, on 8 patients. The first patient died on the second day in hyperthermic coma after exploration of the posterior cerebral fossa. The second patient died of purulent meningitis a few weeks after the operation, and the third patient died after 40 days. The fourth patient, who most likely had a neoplasia of the cerebral trunk, died 19 months after the operation. The fifth patient, who had been dismissed from the hospital after a normal postoperative course and disappearance of the hypertensive syndrome, was lost sight of. The remaining 3 patients were found to be in good condition 28, 27, and 12 months, respectively, after the Torkildsen operation.

A Statistical Comparison Between the Future Condition of Patients with Mitral Valve Disease Operated On and of Those Not Operated On. E. Donzelot, R. Heim de Balsac, P. Samuel, and E. Beyda. Semaine hôp. Paris 34:2855-2858 (Nov. 28) 1958 (In French) [Paris].

The authors report on 322 patients with disease of the mitral valve, who were examined or operated on between February, 1951, and September, 1954, and whose conditions were followed for from 20 months to 5 years. One hundred sixty-five patients were operated on, and 157 were not. Those who did not undergo surgery were assigned to 4 categories. In the first category were 120 patients who were not in operable condition because of large valvular lesions, hypertension, or nonreducible cardiac insufficiency. Although 59 of these patients died, 61 are still living but have had to limit their activities. The 7 patients in the second category included those with such temporary contraindications to operation as progressive renal tuberculosis, pulmonary tuberculosis, bacterial endocarditis, and bouts of rheumatism. Three of these patients later underwent commissurotomy, 3 others soon will, and the 7th patient is still in inoperable condition. The 11 patients in the third category were classified as having a mitral stenosis which was not serious enough to warrant operation. [The cross-sectional area of the mitral aperture must be not less than 2 sq. cm. if it is to permit sufficient flow of blood; patients with stabilized mitral valve disease are much more numerous than the statistics show, because many of them do not consult a physician.]

The fourth category consisted of 19 patients whose mitral stenosis indisputably indicated a commissurotomy but who were not operated on. In this group 12 refused intervention, 6 agreed to it but postponed the operation, and 1 died before he could be prepared for surgery. All 19 patients in category 4 were considered candidates for operation in accordance with the same criteria which were applied to the 165 patients who underwent surgery. All conditions of age, sex, clinical state, etc. were analogous. The authors have made a valuable comparison between the outcomes in the 19 patients who refused operation and the 165 patients who agreed to it; there were 16 deaths among the latter (or a mortality rate of 9.7%) and 11 deaths among the former (or a mortality rate of 58%). The conditions of 2 patients among the 165 and of 4 among the 19 grew worse. But of the 165 patients who underwent surgery, the conditions of 133 (or 80%) improved, 100 to the point where they could return to work and could lead a normal life.

The gravity of spontaneous evolution of mitral stenosis in its pure form, or in forms associated with a mitral insufficiency or another lesion, is evident from the fact that 50% or more of these patients die within 5 years if there is no intervention. The change brought about by commissurotomy shows the great value of this intervention.

Possibilities and Limitations of Induced Hypothermia in Operation on the Bloodless Heart: Experimental Study. A. Martelli, E. Belelli and L. Urso. Clinica 18:301-316 (no. 5) 1958 (In Italian) [Bologna, Italy].

Direct intracardiac surgery by induction of hypothermia was experimentally studied in 20 dogs, divided into 5 groups. All the dogs were immersed in an iced bath until the rectal temperature reached 30 C (86 F). Then the chest was opened through the 4th right intercostal space; this procedure was followed by arrest of circulation, incision and closure by suture of the right atrium, and rewarming to normal body temperature. Of 4 dogs in the first group, arrest of circulation lasted between 5 and 15 minutes in 2 dogs. Sinus rhythm was restored in one dog, and defibrillation through massage and electric shock was required in the other dog. Irreversible fibrillation took place in the remaining 2 dogs, in which circulatory arrest lasted longer than in the first 2.

Cannulation through the subclavian or the right carotid artery and injection of oxygenized blood into the coronary arteries were added to the preceding procedure in the second group of 4 dogs. Irreversible and fatal ventricular fibrillation developed in all 4 dogs. Arrest of circulation was preceded by injection of procaine hydrochloride into the node of Keith and Flack in the third group of 3 dogs. This method was useful in preventing fibrillation, and sinus rhythm was restored in all 3 dogs. Cardiac and circulatory arrests were induced by the administration of potassium citrate in heparinized blood according to the technique of Melrose in the fourth group of 4 dogs and by administration of acetylcholine according to the technique of Moulder in the fifth group of 5 dogs. Ventricular fibrillation, which was mostly irreversible, took place in the dogs which received potassium citrate. No ventricular fibrillation was observed in the dogs which received acetylcholine. The authors conclude that hypothermia has limited application in surgery despite the use of drugs for prevention of ventricular fibrillation.

The Treatment of Papillary Carcinoma of the Thyroid Gland. O. H. Beahrs and L. B. Woolner. Surg. Gynec. & Obst. 108:43-48 (Jan.) 1959 [Chicago].

Views on methods of management of carcinoma of the thyroid vary widely. Some physicians are of the opinion that certain malignant lesions should not be treated surgically at all; some advise only conservative surgical measures, while others recommend radical surgery. In general, carcinomas of this gland can be divided into 2 groups: (1) those of low degree of malignancy, the majority of which are papillary carcinomas, and (2) those of high degree of malignancy, the anaplastic carcinomas. The behavior pattern of each group is decidedly different from that of the other. As currently defined, in the section of surgical pathology at the Mayo Clinic, papillary carcinoma is a well-differentiated tumor which usually shows a striking mixture of papillary and follicular structural components. Within the papillary group there is considerable variation in size of the primary lesion and the degree of invasiveness of the tumor. Certain papillary carcinomas may be minute, even microscopic, and yet be associated with bulky nodal metastasis.

This study was undertaken to evaluate a series of patients with papillary lesions, who had been included in a 1951 report from the Mayo Clinic concerned with patients who had been treated for carcinoma of the thyroid between 1938 and 1947 inclusive. The records of the 174 in whom the lesions were previously classified as papillary carcinoma were restudied. Twenty-four patients were excluded, the lesions in most of them being angioinvasive follicular and solid carcinomas or papillary adenomas. In 136 of the remaining 150 cases, definitive surgical treatment was carried out. Thirteen patients had inoperable lesions, and biopsy only was performed. One patient had palliative lobectomy; at the time of operation gross carcinoma remained in the midline portion of the neck. The treatment and survival rates for the 136 patients who received what was thought by the surgeon to be curative surgical treatment have now been evaluated.

Lobectomy on the side of the lesions or subtotal thyroidectomy was performed on all the patients except 2 on whom total thyroidectomy was done. Metastasis to cervical nodes occurred in 47.1%. The patients were treated by modified neck dissection, except in 5 instances in which radical neck dissection was carried out. No cervical procedure was done for patients who did not have clinically involved cervical nodes or for those in whom nodes could not be felt at the time of operation. The 5-year survival rate was 97%; the 10-year rate, 87.9%; and the 15-year rate, 75.5%. These results support the belief that radical operation is not always essential in the management of papillary carcinoma of the thyroid and that neck dissection is not indicated in the absence of known enlarged cervical nodes.

A Report on Studies of Spinal Traction. G. A. Lawson and C. M. Godfrey. M. Serv. J. Canada 14:762-771 (Dec.) 1958 [Ottawa].

Four factors have been suggested as contributing to the effect of traction on painful back and neck conditions: (1) immobilization, (2) reduction of muscle spasms, (3) reorganization of disk material, and (4) vertebral realignment. In commenting on these factors, the authors say, with regard to immobilization, that many backaches get better if the patient goes to bed for 3 weeks. With regard to release of muscle spasm, it has been observed that stretching a painfully tight muscle gives relief from pain. Some investigators have shown by diskogram studies that there is some sucking back of extruded nuclear material into the center of the disk on traction. Regarding separation of the vertebrae, there has been considerable conjecture. The authors cite figures on the range of weights applied and on the duration of traction applied to different parts of the spinal cord. They examined with the aid of x-rays a group of patients before and during cervical or lumbar traction. The films were read without any knowledge of the order in which they had been taken. The roentgenologist attempted to measure the amount of vertebral separation on each film. The reports were appended to the x-ray films and only then was the roentgenologist told which films were taken before and which during traction.

For cervical traction, the authors used an overhead suspension with a bar and a head sling. The patient was seated with his back to the suspension apparatus, and traction was applied by means of a spring-lift scale to the amount and time decided upon. Usually 40 to 60 lb. of traction for 20 minutes was given, a film was taken, and then in some cases 100 lb. was applied for 1 minute with a follow-up film. In 2 patients films were taken before and during horizontal traction. All patients had received traction previously and were relaxed during investigation. For lumbar traction, a canvas hammock-type of traction frame was used. Not only were roentgenologic control films taken, but the height of the patient before and after cervical traction was ascertained. Height measurements were made on 36 patients, who received at least 10 traction treatments, and roentgenologic studies were made on 26 patients. It was found that spinal traction with weights up to 100 lb. on the cervical area and 150 lb. on the lumbar region for varying amounts of time resulted in no significant separation of the vertebrae. Cervical traction resulted in a slight temporary increase in height.

Spontaneous Perforation of the Common Bile Duct: Report of a Case. T. C. Gertz. A. M. A. Arch. Surg. 78:7-11 (Jan.) 1959 [Chicago].

The author reports on a 4½-month-old female infant who had had jaundice of varying intensity since she was 5 weeks old. The stools were acholic, and the urine contained only traces of bile pigments. The abdomen was distended with ascites. The patient had large bilateral inguinal hernias containing fluid. The abdomen was opened through a transverse incision in the epigastrium. On opening, large amounts of bile-stained fluid escaped. The stomach and the duodenum were adherent to the lower surface of the liver and obscured the porta hepatis and the ligament. They were dissected free in order to gain access to the hepatoduodenal ligament. In this procedure a large cavity was entered, the walls of which consisted of heavily bile-stained fibrous and fibrinous tissue. The cavity contained traces of clear bile. Through a puncture of the gallbladder, the gallbladder and the bile ducts were filled with iodopyracet (Diodone), and a cholecystocholangiogram was taken which showed an evident leakage in the inferior part of the common bile duct and an obstruction of the passage to the duodenum. It was not possible to localize the perforation. A rubber tube was placed in the region of the common duct, and the abdomen was closed in layers. Postoperatively, there was profuse drainage of bile for some days, but after 9 days this gradually ceased and the drain was removed. A month after the surgical intervention, the patient was discharged in excellent condition. The inguinal hernias disappeared spontaneously after the operation.

Ten additional cases of spontaneous perforation of the common bile duct in infants between the ages of 3 weeks and 22 months were collected from the literature. The findings in these patients and in the author's patient showed that spontaneous perforation of the common bile duct is a disease typically characterized by a mild, intermittent jaundice, acholic stools, absence of bile pigments in the urine, distended abdomen with ascites, and, very often, bilateral inguinal hernias with fluid. Although the disease may run acutely, the course is mostly subacute. If the disease is let alone, it is occasionally fatal; usually, though, it responds well to surgical intervention, which ought to be performed as soon as the diagnosis has been made. Simple drainage of the region of the common duct has in most patients been adequate. Operative cholecystocholangiography is a valuable diagnostic method.

Prevention and Treatment of Infections in Bone. J. H. Moe. Journal-Lancet 79:2-7 (Jan.) 1959 [Minneapolis].

The author reports the case of a 48-year-old woman with a comminuted fracture of the right lower femur for which she was treated by open reduction and internal fixation with a nail and plate combination. Wound infection occurred despite administration of large daily doses of antibiotics. The operative wound was opened, and evidence of purulent osteomyelitis was found. Amputation through the middle of the thigh was advised but refused by the patient. For one year numerous attempts were made to control the infection without amputation. Rush pins were inserted 10 days after the initial débridement and removal of plate and screws. The wound did not become clear. A high thigh amputation performed with the consent of the patient proved inadequate, and a disarticulation of the hip finally became necessary to control the infection. Plate-and-screw fixation does not serve as a satisfactory method of fixation in the presence of osteomyelitis. The screws loosen, the drill holes become filled with granulation tissue, and the bone becomes necrotic under the plate. A second case of a comminuted fracture of the femur in a 32-year-old man is reported, with satisfactory outcome of a severe infection of the operative wound. The infection had occurred after open reduction with double-plate fixation without external support, requiring 4½ hours because of an inadequate armamentarium of equipment. Plate-and-screw fixation was removed when the wound was opened and débrided. All dead tissue and some bone were removed. This procedure was followed by packing the wound and irrigating it while maintaining position of the fracture by traction in suspension. After one week an intramedullary nail was inserted, and open packing and irrigation with sodium chloride solution and antibiotics were continued for an additional week. Specific antibiotics were given systematically. Subsequently, secondary closure was successful in obtaining soft tissue coverage, with minimal drainage from a small sequestrum visible 2 months later. The wound healed after sequestrectomy.

Excessive operating time in surgical open reduction of fractures invites infection. The use of plates and screws without external fixation provides inadequate internal fixation in comminuted fractures of long bones. Wound infections in open fracture surgery should not be treated expectantly. The surgical principles of complete exposure of the infected area, eradication of the grossly necrotic tissue, removal of all plates and screws, and open packing of the wound for easy dependent drainage are sound. Maintaining position of the fracture fragments and instituting specific antibiotic medication, both locally and systemically, are also of importance. The optimum time for secondary closure is about 5 to 10 days. When secondary closure is done, the wound must be completely obliterated of dead space. Intramedullary nail fixation can be instituted in the presence of infection without hazard. On the other hand, plates and screws are not well tolerated. When bone sequestrates, the necrotic portion must be removed.

The prevention of infection in compound fracture wounds is directly related to the initial care given the wound. Only wounds which are very fresh and thoroughly cleansed should be closed primarily, and such closure must be done without tension. All wounds several hours old and those which are doubtfully clean should be packed open with fine mesh gauze and closed secondarily. External support to the fracture by cast or suspended splinting should always be given. The prevention and control of infections in bone as well as in soft tissue in hospitalized patients require constant vigilance and good surgical judgment. Team work on the part of physicians, nurses, and personnel is of utmost importance. The salient features of a program directed toward eradicating infections are outlined.

The Removal of Excessive Potassium and Ammonium from Bank Blood Prior to Transfusion. D. C. Schechter, T. F. Nealon Jr. and J. H. Gibbon Jr. Surg. Gynec. & Obst. 108:1-6 (Jan.) 1959 [Chicago].

Blood undergoes certain biochemical changes during storage, the most significant of which, for the recipient of the blood, are the greatly increased concentrations of ammonium and potassium. The authors investigated this increase and describe a simple method for removing excessive potassium and ammonium from stored blood prior to transfusion. They collected from the cubital vein of each of 27 male volunteers 500 ml. of whole blood. A sample was withdrawn for chemical analysis, and the remainder of the blood was stored at 5 C. The blood from 9 of these men (group A) was collected in 500-ml. silicon-coated vacuum bottles (Transfuso

Vac), containing 120 ml. of acid-citrate-dextrose solution, U.S.P. formula B. Three bottles were stored for 7 days, 3 for 14 days, and 3 for 21 days. The blood from 9 subjects (group B) was collected in plastic bags (acid-citrate-dextrose blood pack), containing 75 ml. of acid-citrate-dextrose solution, U.S.P. formula A. These likewise were stored for periods of 7, 14, and 21 days. Blood was drawn from 9 subjects, group C), passed through a cation-exchange resin, and then stored in a plastic container (ion-exchange blood pack) for periods of 2, 5, and 10 days. The shorter time intervals were selected for this group because 10 days is the upper limit of cell survival under these conditions.

At the completion of the various periods of storage the blood was removed from the refrigerator. A sample of the blood was taken for analysis, and the remainder of the blood was passed through a resin column. The resin columns used consisted of 50 Gm. of Dowex 50-X8, sodium cycle, supported on 100-mesh nylon bolting cloth, in a vinylite casing. The columns were connected to the blood containers. The cold blood was passed over the resin at room temperature to simulate conditions prevailing during most clinical transfusions.

It was found that there is a progressive increase in ammonium and plasma potassium in blood stored in siliconized vacuum bottles and plastic containers. These ions accumulated more rapidly in blood decalcified by passage through an ion-exchange column than in blood to which acid-citrate-dextrose solution has been added. Passage of stored blood across a cation-exchange resin consistently reduced the concentrations of plasma potassium and blood ammonium to, or below, normal levels. This reduction was accompanied by a small increase in the plasma sodium concentration. This simple method is recommended as a means of effectively removing excessive potassium and ammonium from bank blood prior to transfusion.

Dispensability of Post-Operative Penicillin in Septic-Hand Surgery. J. Anderson. Brit. M. J. 2:1569-1571 (Dec. 27) 1958 [London].

In an attempt to evaluate the common use of penicillin after surgical interventions on septic lesions of the hand, the author studied the postoperative care given to 357 outpatients with sepsis of the hand. Of the 357 patients, 106 did not receive any chemotherapy, 110 were given penicillin orally, 104 received penicillin by intramuscular route, and 37 were excluded from the study because of complications, failure to return for dressings, or chronic infections. The types of the lesions in the 320 patients included paronychia in 102, onychia in 31, pulp abscess in 82, other abscesses in 94, and septic blister in 11. The respective healing times in the 3 unselected postoperative treatment groups were 9.4, 9.5, and 9.2 days.

The reduction in the over-all average healing time of less than a quarter of a day in the patients receiving penicillin by intramuscular route as compared with the group receiving no chemotherapy, under the conditions of the study, does not justify the administration of penicillin postoperatively without a special reason. Careful clinical examination, accurate diagnosis, and precise surgical intervention are of greater importance than routine chemotherapy. Routine postoperative administration of penicillin does not hasten healing in septic lesions of the hand which require surgical treatment, provided that a careful technique is based on anatomically accurate diagnosis. Penicillin has been safely excluded from the postoperative environment of uncomplicated acute infections of the hand, and this may be a more fundamental counter to the emergence of resistant organisms than recourse to other antibiotics. Possibly web abscess and threatened infection of the structures that move or support the hand are the only firm indications for chemotherapy, which will not act as a cover for erroneous diagnosis or inappropriate surgical intervention.

A Six Year Study of Incompatible Blood Transfusions. L. S. Binder, V. Ginsbert and M. H. Harmel. Surg. Gynec. & Obst. 108:19-34 (Jan.) 1959 [Chicago].

At the Kings County Hospital Center, Brooklyn, N. Y., 81,392 blood transfusions were administered during the 6-year period from 1952 to 1957. This study is concerned with observations on the 30 patients who received transfusions of improper blood. In 28 of these 30 patients it was proved that incompatible blood had been transfused. Twenty-six of the incompatibilities were in the ABO antigen system and 2 in the Rh system. The nature of the incompatibility could not be established in the remaining 2 patients, but as they had clinical and laboratory evidence of hemolysis, they are included in this series. The total incidence of incompatible blood transfusions in this hospital center was 1:2,713 (30:81,392). This figure differs from the incidence of hemolytic transfusion reactions, because 12 of the 30 patients did not have such a reaction. Of the 18 patients who were proved to have had a hemolytic transfusion reaction (an incidence of 1:4,520), 7 patients died, but in 5 of them the appearance of a coagulation defect contributed significantly to the deaths.

Although the role of renal ischemia in the pathogenesis of renal failure cannot be ruled in or out, the clinical parameters generally associated with decreased renal blood flow, i. e., shock and blood loss, could not be correlated with the production of kidney shutdown. Four phases have been differentiated in the clinical course of hemolytic transfusion reaction: an initial phase of clinical symptoms;

the interval phase of apparent clinical improvement associated with oliguria; the phase of renal failure identified with stupor, convulsions, and coma; and the phase of recovery heralded by the abrupt onset of diuresis. Each is variable in severity and duration, and one or more may be either clinically insignificant or lacking entirely. As the patient progresses through each phase, the therapy is varied to meet the changing clinical problem.

It was impressive how efficacious the high-calorie, protein-sparing, fluid-and-potassium-limited diet was in preventing uremia. Pulmonary edema and congestive heart failure due to hypernatremia and overhydration did not occur. Hyperkalemia may have been of clinical importance in one patient, and only in this instance might hemodialysis or peritoneal dialysis have been a necessary procedure. Once diuresis occurred, fluid administration was increased to match the output. To prevent dehydration and hypochloremia, attention was directed to sodium and chloride replacement.

In spite of vigorous treatment of patients in whom hemorrhagic diathesis developed, the results were eminently unsatisfactory. Therapy was directed toward 3 goals: (1) restoration or maintenance of the blood volume by energetic transfusion; (2) support of the blood pressure when necessary with vasopressors; and (3) correction of the clotting defects with fibrinogen, fresh-frozen plasma, or whole blood newly withdrawn. Yet none of the patients treated in this manner survived. The causes of incompatible blood transfusions and measures for reducing them are evaluated.

GYNECOLOGY & OBSTETRICS

Intrauterine Bacterial Infection of the Newborn Infant: Frozen Sections of the Cord as an Aid to Early Detection. K. Benirschke and S. H. Clifford. J. Pediat. 54:11-18 (Jan.) 1959 [St. Louis].

The authors report the histories of 2 newborn infants, illustrating bacterial infection of the fetus as an important cause of perinatal mortality and morbidity. While prolonged rupture of the membranes and prolonged labor are frequently associated with fetal infection, it may occur with intact membranes and be absent in instances of prolonged rupture. Fetal infection is probably acquired through an ascending infection of the amniotic cavity. According to the authors' experience, the fatal cases of fetal infection have all been associated with inflammation of the amniotic sac.

The frozen-section method described has proved to be a rapid and reliable means of determining, in suspected cases, the presence or absence of cord vasculitis. It frequently demonstrates the presence of actual organisms. The absence of inflammation may under certain circumstances suggest a viral infection. Frozen sections of the cord may enable the clinician to exert better judgment as to what method of treatment should be used. The indication for active treatment may be lifesaving for many infants days before the appearance of obvious clinical signs.

X-Ray Pelvimetry. E. A. Graber, H. R. K. Barber and J. J. O'Rourke. Am. J. Obst. & Gynec. 77:28-33 (Jan.) 1959 [St. Louis].

More than 200 different methods of x-ray pelvimetry have been advanced in the past 58 years. According to its advocates, modern roentgenologic pelvimetry has almost achieved the ultimate in accuracy and usefulness. This study scrutinizes the validity of this belief. Since practically all pelvimetric x-ray examinations in New York are interpreted and reported by roentgenologists, it was decided that the best way to arrive at an unbiased conclusion was to get pelvimetry reports from many different roentgenologists. This report is based upon 242 pelvimetries and deliveries. Roughly, this represents about 15% of the total number of deliveries. The methods of roentgenologic evaluation utilized were those of Thoms, Ball, Snow, Colcher and Sussman, and Caldwell and Moloy. These are the popular techniques in New York and are all about equal in accuracy. The indications for x-ray pelvimetry in this series were rather loose. The intention was to get as wide a sampling as possible of normal and abnormal pelves. Some of the x-rays were taken about one week from term, and some were taken when the patient was in labor.

The 242 roentgenologic pelvimetries, which were made by 18 different roentgenologists, were reviewed with regard to the prognostic accuracy of the reporting physician. Three out of 4 were reported correctly, but almost all of these were in the adequate pelvis with an average-sized baby. Since the roentgenologist has no method of measuring the fetal head adequately, he was in error most frequently in cases in which the obstetrician needed help—cases of cephalopelvic disproportion due either to a borderline pelvis or to an unsuspected larger baby in an average pelvis.

It is suggested that the roentgenologist does not usually have sufficient information or the obstetric background to make a clinical prognosis and should cease predicting the outcome of delivery. Furthermore, by his predictions, he places the obstetrician in an untenable position medicolegally. X-ray pelvimetry was never intended to take the place of an adequate pelvic examination in labor, and a trial of labor. It is a laboratory aid at best and should be used as such. Roentgenologic pelvimetry should be limited to 2 situations: (1) malpresentation, and (2) lack of adequate clinical progress in labor. The authors feel that x-rays should be taken only while the patient is in labor for maximum information. Since all radiation is harmful, all routines as to the number of plates should be discarded. A specific minimum number of views should be ordered by the obstetrician for the individual patient.

Megaloblastic Anaemia of Pregnancy and the Puerperium. C. Giles and E. M. Shuttleworth. Lancet 2:1341-1347 (Dec. 27) 1958 [London].

Of 3,199 pregnant women who were delivered at the City General Hospital in Stoke on Trent, England, and at the allied Limes Maternity Hospital, between March 1, 1957, and May 31, 1958, 474 with an arbitrary hemoglobin level of 9.5 Gm. per 100 cc. (65%) or less were studied by sternal puncture. Of the 474 patients, the bone marrow was found to be megaloblastic in 90 and normoblastic in 372; in the remaining 12 patients megaloblastic anemia was suspected, but a firm diagnosis could not be established. In 28 of the 90 patients with megaloblastic anemia, the megaloblastic marrow was found in the puerperium. Seventy-two (80%) of the 90 patients, whose average age was 28.9 years, were multiparas, and 7 (7.8%) of the 90 gave birth to twins, as compared with 9 twin deliveries (2.4%) among the 372 patients with normoblastic anemias, thus confirming previous reports of the higher incidence of megaloblastic anemia in multiple pregnancies. In patients with a hemoglobin level of less than 6.5 Gm. per 100 cc. (45%), the anemia was more frequently megaloblastic than normoblastic.

Of 67 patients in whom test meals were carried out, 26 (37%) had achlorhydria, and fat absorption was impaired in 4 patients. No special seasonal incidence of megaloblastic anemia was noted. Gastrointestinal symptoms were uncommon, and the incidence of complications, such as preeclamptic toxemia and obstetric hemorrhage, was not substantially higher among the patients with megaloblastic anemia than among those with normoblastic anemia. In 38 (42%) of the 90 patients with megaloblastic anemia, the diet was poor, compared with 12% on a similar diet among the patients with normoblastic anemia and 4% among healthy controls. The difference was even greater, when the intake of meat was compared. No local factors could be discovered to account for the high incidence of megaloblastic anemia in this series. All the patients were treated with folic acid. The reticulocyte peak and the drop in the serum iron level reflected the response to treatment in most of the patients.

Survival of Female Patients with Cancer of the Breast: A Study of the Effects of Demographic and Economic Factors. B. D. Waxman and W. T. Fitts Jr. Am. J. Surg. 97:31-35 (Jan.) 1959 [New York].

Of 633 women with a pathological diagnosis of cancer of the breast, who were treated primarily at the Hospital of the University of Pennsylvania in Philadelphia between 1943 and 1951 and whose average age was 53.7 years, 67% were married, 16% were widowed, 13% were single, and 4% were divorced. Thirty-six per cent were ward patients, 46% occupied semiprivate rooms, and 18% were in private rooms. The type of room patients occupy in a hospital is probably a good index of their economic condition. Analysis of the relationship between economic status, as measured by the type of room occupied, and the duration of symptoms at the time the patient reported them revealed striking differences. While only 20.6% of the ward patients reported their symptoms within one month, 36.2% of the private patients reported their symptoms early. This difference is significant and is considered strong evidence that economic status is positively correlated with early reporting of symptoms. A significant increase was noted in the proportion of ward patients reporting symptoms of one month's duration in the period from 1947 to 1951 as opposed to the period from 1943 to 1946. This finding indicates that publicity about cancer is having a significant effect in reducing the duration of symptoms for the lower economic strata.

Of 191 women with cancer of the breast who were followed up for 5 years, 67% of those with a duration of symptoms of less than one month survived 5 years, as opposed to 60% with a duration of symptoms of 1 to 2 months, 56% with a duration of 3 to 5 months, 45% with a duration of 6 to 9 months, and 37% with a duration of 10 months and more. These data indicate that patients who report cancer symptoms early have a better chance of survival. Although the authors did not demonstrate a statistically significant relationship between economic status and survival when the Chi-square test was employed, the reported observations suggest that there may be an economic factor working indirectly on survival through a differential time lag in the reporting of symptoms.

PEDIATRICS

An Appraisal of Fulminant Meningococcemia with Reference to the Shwartzman Phenomenon. W. Margaretten and A. J. McAdams. Am. J. Med. 25:868-876 (Dec.) 1958 [New York].

Of 52 children with fatal meningococcic infection who died at the Cincinnati Children's Hospital between 1937 and 1956, autopsies were performed on 40. The meningococcus organism was identified by culture or smear in 34 of these 40 patients, and in the remaining 6 autopsy revealed the classic features of the Waterhouse-Friderichsen syndrome, as well as the typical purpura of meningococcemia. The adrenal glands were examined in the course of autopsy in all 40 patients and were considered to be typical of the Waterhouse-Friderichsen syndrome in all but 4 patients in whom purulent meningitis was the cause of death. Sections of kidney also were studied in all 40 patients. Thrombi, either glomerular, intertubular capillary, or both, were observed in 9 patients. In 3 of these patients there was also bilateral cortical necrosis. These 3 patients were not in shock at the time of admission to the hospital and received some form of adrenocortical steroid before the development of shock, suggesting a direct relationship of the renal cortical necrosis to adrenal steroid therapy. This occurrence and the apparent causal relationship of thrombosis in the production of the hemorrhagic lesions of the skin and adrenals in the Waterhouse-Friderichsen syndrome suggest that the Shwartzman phenomenon may be responsible for certain manifestations of fulminant menigococcemia. The apparent rarity of renal cortical necrosis in meningococcic infection in man, a lesion that is characteristic of the generalized Shwartzman reaction in rabbits, suggests that the common skin and more occasional adrenal lesions of this disease may be produced by the local Shwartzman phenomenon.

The cases of the 52 children with fatal meningococcic infection were compared with 152 consecutive bacteriologically proved cases of meningococcemia in which the patients survived. Of the 204 patients, virtually all received intensive antibacterial therapy, but only 63 received some form of adrenal steroid therapy. Considering only the 166 patients who were not presumed to be in shock at the time of admission, there was a striking difference in outcome: the mortality rate among the patients receiving steroid therapy was 21% as compared with a 7% mortality rate among those not so treated. These observations, as well as those in the 3 patients with fatal meningococcemia and bilateral renal cortical necrosis, imply that a deleterious rather than a beneficial effect may result on occasion from the use of adrenal steroid therapy in patients with fulminant septicemia.

Enteroviruses and Diarrhoea in Young Persons. R. G. Sommerville. Lancet 2:1347-1349 (Dec. 27) 1958 [London].

During one year from April, 1957, a single stool specimen was obtained on admission from each of 338 children, all aged 5 years or less, who were admitted with diarrhea to the Ruchill Hospital in Glasgow. Seventy-five enteroviruses were isolated from the stool specimens of these patients, and 17 enteroviruses were isolated from the stools collected from 115 children of similar age, admitted with respiratory infections to the same hospital during the same period and serving as controls. The proportion of poliomyelitis viruses and Coxsackie viruses was similar in the children with diarrhea and in the controls, but the number of enteric cytopathogenic human orphan (ECHO) viruses isolated from the children with diarrhea was greater (although not significantly) than in the controls. The enteroviruses isolated included 3 types of poliomyelitis virus, Coxsackie B1, B3, and A9, and ECHO 6, 7, 9, 11, and 13. The most frequently observed types were ECHO 7, Coxsackie A9, and poliomyelitis 1. In 23 patients an enterovirus and a pathogenic bacterium were isolated from the same stool specimen. The commonest combination consisted of Shigella sonnei and either ECHO 7 or Coxsackie A9. A virus was isolated from 22%, and a specific intestinal pathogenic bacterium from 36.5% of the children with diarrhea, making a total isolation rate of 58.5% for the whole group of 338 children. The total isolation-rate, considered in relation to the ages of the patients, was lowest (44.5%) among children aged less than 1 year, but averaged 80% among children between the ages of 1 and 5 years.

Heart Failure in Infants. K. Simpson. Proc. Roy. Soc. Med. 51:1022-1023 (Dec.) 1958 [London].

The records of 50 infants admitted to the hospital with heart failure were reviewed to determine early signs of failure and to assess the incidence of respiratory infection. The reason for referral was noted in 40 infants. Although 26 of these were in failure when they were first seen, a diagnosis of heart failure was made in only 1 before admission. In two-thirds of the infants heart disease had not previously been suspected, diagnoses implying respiratory disease or feeding difficulty being made. Regarding the final diagnoses, the author states that in 10 infants no congenital cardiovascular anomaly was detected, whereas in the other 40 infants heart failure occurred with congenital heart disease. In 6 of the 10 infants without congenital defect, heart failure developed with acute pulmonary infection; in 4 infants failure was associated with cardiac arrhythmia. Nineteen of the 40 infants with congenital heart disease had lesions for which operation offers, or may soon offer, a prospect of improvement or cure (venticular septal defect, patent ductus arteriosus, pulmonary stenosis, coarctation of aorta, and tetralogy of Fallot); 14 of these 19 infants have recovered from heart failure.

Enlargement of the liver was a frequent clinical feature, being present in 40 of the infants. Respiratory disturbances were noted in 42. Tachypnea at rest was an early sign of cardiac failure and often preceded hepatomegaly by many hours, the respiratory rate rising rapidly and progressively. Cardiac enlargement was found in 27 infants. Venous distention was seen in 14 infants. Indisputable edema was present in 12 infants. In 5 of these, heart failure was not associated with congenital heart disease, and all recovered. The remainder, who had congenital cardiac anomalies, died. Rales were heard in 27 infants. When tachypnea is associated with fever or with pulmonary rales in an infant who has congenital heart disease, the differentiation of heart failure from respiratory infection is extremely difficult, and the 2 conditions frequently coexist.

The assessment of infection was based on the history, occurrence of coryza, presence of pulmonary rhonchi, clinical pathological data, and roentgenologic and postmortem evidence. No evidence of infection was found in 21 cases; 14 infants in this group died, the majority having severe and complicated malformations. Of 20 infants with respiratory infection, 9 died; 6 of these had cyanotic congenital heart disease. In the remainder pulmonary consolidation or collapse was found. The overall mortality was 48%. Fifteen out of 16 infants, with right-to-left shunts large enough to produce cyanosis, died, the presence of respiratory infection making little difference to the outcome. Of 24 infants with acyanotic congenital heart disease, 8 died. In this group infection probably played a bigger part in precipitating failure.

Prematurity and "Cerebral Palsy." P. E. Polani. Brit. M. J. 2:1497-1499 (Dec. 20) 1958 [London].

That there is an association between prematurity and cerebral palsy impressed the earliest students. The nature of this association is not clear, but the author shows that for some investigators the effect of prematurity is to cause a developmental anomaly of the pyramidal tracts; for others, the two conditions are parallel manifestations of an intrauterine abnormality causing both prematurity and primary antenatal degeneration of cerebral neurons. Since cerebral palsy is an aggregate of clinical syndromes with various origins, the author suggests that one might expect some types of cerebral palsy to be more strongly associated with prematurity than others.

Reviewing the incidence of prematurity in various clinical types of cerebral palsy, the author found a particularly strong association with 2 neurological syndromes: (1) dystonic/choreoathetoid cerebral palsy after severe neonatal jaundice not due to blood-group incompatibility, and (2) cerebral spastic [illegible]. The possible mechanisms [illegible] are considered, and a selective developmental origin for the neurological troubles is favored tentatively. Because of the association between retrolental fibroplasia and cerebral spastic paraplegia/diplegia, and because of the clinical features of the cerebral spastic paraplegia syndrome without history of perinatal or postnatal troubles, a postnatal interference with development is the mechanism postulated for this clinical type of cerebral palsy. Although the suggestion that premature birth may at times cause postnatal interference in development and maturation of critically maturing neurons is entirely hypothetical, it can be put to the test by experiments with high-oxygen pressures in immature animals.

Spiramycin in the Clinical Treatment of Infants. P. Caruso and S. La Rocca. Clin. pediat. 40:663-687 (Aug.) 1958 (In Italian) [Bologna, Italy].

A study on the effect, in vitro and in vivo, of spiramycin is reported. In vitro, the drug proved very effective in inhibiting hemolytic and fecal pneumococci. The clinical study was made on 24 children, between the ages of 5 months and 11 years, with acute bronchopneumonia. Spiramycin was administered in an initial dosage of 100 mg. per kilogram of body weight per day, divided into 2 or 3 equal subdoses and combined with large quantities of vitamin C and vitamin B complex. Eight of the children had been treated previously with other antibiotics but with no beneficial effect. The spiramycin therapy was followed by clinical recovery in all the children. There was a drop in temperature 24 to 72 hours after the beginning of treatment; in only one child did a high temperature persist for 6 days. Clinical symptoms regressed after 2 to 8 days of treatment. Recovery was faster in those children who had been treated previously with other antibiotics. Spiramycin had no toxic effect and was well tolerated by all the patients.

Large Abdominal Lumps in Children with Particular Reference to Embryoma of the Kidney: A Survey of 100 Consecutive Cases. J. H. Louw. Med. Proceed. 4:801-809 (Dec. 13) and 832-837 (Dec. 27) 1958 [Johannesburg, South Africa].

Discussing the general problem of large abdominal tumors in childhood, the author gives particular attention to Wilms's tumor, pointing out that embryoma of the kidney (nephroblastoma) has been most aptly described as "a tremendous tumor with a tiny child attached to it." The author reviews observations on 100 consecutive children who presented with large abdominal masses at the children's surgical units of Groote Schuur Hospital and the Red Cross Children's Hospital of the University of Cape Town over the past 7 years. Nearly half of the 100 children with large abdominal lumps had malignant disease, and nephroblastoma accounted for half of these. Malignant disease is not uncommon in childhood, and its possible existence should constantly be borne in mind. The age group of 1 to 4 years appears to be particularly prone to malignant disease. In considering the 100 children with abdominal swellings, the incidence of malignant swellings in this group was 8 times greater than that in infants under 1 year, and 4 times that in children of 5 years and over. In the age group of 6 months to 6 years, almost 80% of the swellings were malignant. More than 95% of the abdominal malignancies occurred in this group, and so did all the nephroblastomas in this series. In the group ranging in age from birth to 6 months, most of the swellings were due to serious congenital malformations. In the group 6 years of age and over, chronic inflammation and benign tumors and cysts accounted for 75% of the swellings.

Early diagnosis depends first on routine palpation of the abdomen of every child who is brought for any examination. If an abdominal lump is found, intravenous pyelography is usually necessary. Exploratory laparotomy should be performed on all children in whom a neoplasm is suspected or when there is doubt about the diagnosis. The prognosis of malignancy in children is unfavorable; if it occurs in the abdomen, less than one-third of the children survive 5 years. This applies particularly to nephroblastoma. Surgical removal still offers the best chance of survival, particularly in nephroblastoma. Radiotherapy is a valuable adjunct to surgery and should always be used in nephroblastoma. Chemotherapy is of limited value.

UROLOGY

Endocrine-Control Therapy in Prostatic Cancer. J. D. Fergusson. Brit. J. Urol. 30:397-406 (Dec.) 1958 [Edinburgh].

The author reviews observations on 344 consecutive patients with prostatic cancer treated by him over a period of years extending to January, 1958. Urinary symptoms directly referable to the primary growth were observed in 262 of the 344 patients; 55 patients had metastatic manifestations, and a further 9 had a combination of the two. Of the remaining 18 prostatic cancers, some were brought to light on routine rectal examination and a small number by the discovery of cancer in material removed by enucleation prostatectomy. Clinically, 264 patients gave positive evidence of disease at the primary site, while in 80 the rectal findings were negative or equivocal. The diagnosis was confirmed histologically or cytologically in 288 patients and, in the remainder, by the presence of strong clinical evidence supported by roentgenologic and serologic findings. The 288 patients were treated initially with estrogens, supplemented by conservative transurethral resection (when indicated) for the relief of urinary obstruction. Fifty-six patients received no hormones but were otherwise similarly treated. Most of the latter were early cases, and, with the possible exception of 8 patients who could not be traced, all were known to have died before January, 1958. Of the 288 who received hormone therapy, 207 have died, while 81 are surviving.

As a result of his experience with various methods of endocrine-control therapy, the author arrives at the following conclusions: 1. Endocrine-control therapy is selective in action and is insufficient to eliminate prostatic cancer. 2. Approximately 20% of cancers are resistant to the simpler forms of treatment (estrogen therapy and castration). 3. Failure to respond to one form of therapy does not necessarily preclude a response to others, but appears to make this less likely. 4. Different parts of the same tumor may react differently, and this applies also to the primary growth and its metastases. 5. There is no reliable index of hormone sensitivity, and the only prognostic data of value are age and the presence or absence of disseminated disease.

Influenced both by the survival studies and clinical considerations, the author is inclined to advocate initial treatment with high doses of estrogens in all active cases, supplemented where necessary by castration. No treatment is indicated for latent cancer. Subsequent adrenalectomy for relapse or resistance has been abandoned, as the results generally fail to offset the inconvenience of treatment. "Irradiation hypophysectomy," representing an attack on the fountainhead and offering less of an ordeal, is now preferred, but it still remains too uncertain to be used as a primary definitive treatment. Judicious application of endocrine therapy can do more to mitigate suffering in disseminated prostatic cancer than any other method presently at disposal.

Chemotherapy of Renal Tuberculosis. H. Wechsler, J. K. Lattimer, M. A. Garcia and H. Kavookjian. New York J. Med. 59:49-52 (Jan. 1) 1959 [New York].

The authors report on the effectiveness of 3 regimens, with isoniazid, streptomycin, and aminosalicylic acid, in treating patients with renal tuberculosis at the research unit for genito-urinary tuberculosis of the Bronx Veterans Administration Hospital in New York. The results of triple-drug therapy, with isoniazid in doses of 100 mg. 3 times daily, sodium aminosalicylate in doses of 5 Gm. 3 times daily, and streptomycin in doses of 1 Gm. twice weekly, for one year were encouraging (a report on this treatment was published in THE JOURNAL, Feb. 18, 1956, page 544). Less effective were single drug regimens with streptomycin or isoniazid alone. A two-drug regimen with 1 Gm. of streptomycin twice a week and 12 Gm. of sodium aminosalicylate daily was also less effective. Follow-up studies have shown the value of triple-drug treatment. After streptomycin was given alone, patients suffered relapse at a prohibitive rate, with only about 20% of the patients showing conversion of urine cultures to negative by the 5th year of follow-up. The follow-up of patients given streptomycin–aminosalicylic acid therapy revealed a drop to 70% in successful conversions by the 6th year, while 24 (96%) of 25 patients on the three-drug regimen have maintained conversions for 4 years.

Continued observation of the patients for at least 10 years may indicate the optimum therapeutic regimen among the several combinations now under study. Two-drug therapy may be used for lesions of small volume (groups 0 and 1 according to the classification of Lattimer). The advanced cavitary lesions (groups 2, 3, and 4) are now treated with triple-drug therapy—100 mg. of isoniazid 3 times daily, 5 Gm. of sodium aminosalicylate 3 times daily, and 250 mg. of cycloserine twice daily. This treatment is given for 2 years. The patient is usually kept in the hospital during the first 6 to 12 months, but treatment is continued for a second year after his discharge. A semiambulatory rest program is encouraged during the first 6 months of treatment, and rest is encouraged each day. The year in the hospital is also used for rehabilitation and job training for the future. The use of monoxychlorosene, a hypochlorous acid derivative (Clorpactin 90), for local bladder therapy is a helpful adjuvant in relieving the pain from tuberculous ulcers of the bladder. Two new drugs, kanamycin and thiocarbanidin, are now under trial to serve as substitutes for drugs which are difficult to tolerate (aminosalicylic acid) or require injection (streptomycin). The authors have withheld surgical treatment even for patients with advanced renal tuberculosis and will continue to do so unless relapses occur.

THERAPEUTICS

Clinical Research on the Analgesic Action of 2,2-diphenyl-3-methyl-4-morpholinobutyrylpyrrolidine in Dextrose Solution (R 875). A. Pesce, M. Ricciardi and G. Rugiero. Policlinico (sez. prat.) 65:1766-1770 (Nov. 17) 1958 (In Italian) [Rome].

Sixty-two obstetric-gynecologic patients benefited from the analgesic action of 2,2-diphenyl-3-methyl-4-morpholinobutyrylpyrrolidine in dextrose solution (R 875). R 875 was given in several doses of 1 or 2 mg. every 5 to 10 minutes, as a complementary analgesic drug to thiobarbituric acid, to 25 obstetric-gynecologic patients during a surgical operation. This procedure permitted the maintenance of anesthesia during operations lasting more than 2 hours without any further administration of thiobarbituric acid. Twenty-five gynecologic patients received subcutaneously or intramuscularly 5 to 10 mg. of R 875 during 71 episodes of acute postoperative pain after return to consciousness. [These patients had not received R 875 during the operation.] The analgesic effect of R 875 was more intense, and it developed earlier and lasted longer (between 4 and 6 hours altogether) than that of morphine, meperidine hydrochloride, or methadone hydrochloride which were used on other occasions. R 875 was given intramuscularly to 12 women during labor in doses of 10 mg. every 20 to 30 minutes until the threshold of anesthesia was reached. The drug induced an intense analgesic state without affecting mental lucidity of the patients. This effect permitted a cooperative attitude of the parturients during expulsion and reduced the duration of labor. Oral or subcutaneous administration of R 875 produced mild side-effects: pallor, malaise, and nausea accompanied by vomiting. Intravenous administration of the drug brought about more serious side-effects: rapid vertical and horizontal clonic motions of the eyeballs and respiratory disturbances, including apnea. Therefore, it is suggested that the intravenous administration of R 875 be carried out only under the supervision of an anesthetist.

Digestive Hemorrhages and Gastroduodenal Ulcers Caused by Aspirin (with Special Reference to Fifty-two Personal Observations). M. Levrat and R. Lambert. Presse méd. 66:1945-1948 (Dec. 10) 1958 (In French) [Paris].

Mild reactions from digestive intolerance to aspirin are considered banal, but severe digestive complications are not regarded as commonplace. The authors believe that aspirin provokes isolated digestive hemorrhages and is the drug most frequently responsible for ulcerous hemorrhages. Their work is based on observations of 52 patients made in 1957 and 1958. Digestive disturbance usually took place a few hours after the absorption of aspirin, usually within 24 hours. Thirteen of the patients had an ulcerous nonhemorrhagic attack, and in 2 of them the disturbance lasted for several months. In 39 of the patients aspirin caused digestive hemorrhage of the following 3 types: in 15 cases there was roentgenologic proof of an active ulcer; in 21 cases the hemorrhage was isolated and not related to any evident digestive lesion; and in 3 cases there were signs of alcoholic hepatitis.

Ulcerous "terrain" plays a large part in the genesis of these disorders. Altogether 78% of the 52 patients in this series had an ulcerous condition. In 16 of the patients the histaminopexic (histamine-fixing) power was absent in the serum and in the gastric juice. Aspirin occasionally promoted chronic dyspeptic trouble. It provoked reactivation of ulcer without hemorrhage in 13 patients, maintained an ulcerous condition in 2, and caused a perforation in 1. *Digestive hemorrhage is the most frequent* type of digestive disorder from aspirin and was present in 75% of the authors' series. It usually has a benign course. Some statistics are cited, indicating that aspirin is responsible for one-third of ulcerous hemorrhages and for about one-half of isolated digestive hemorrhages, but the series was too small to be entirely reliable.

The pathogenic mechanism of the disturbance caused by aspirin proceeds from the corrosive action of the gastric contents combined with the presence of insoluble particles. The action is general and is harmful to a predisposed mucous membrane. Experiments by the authors on 200 rats resulted in superficial and hemorrhagic lesions of the gastric mucosa after oral or parenteral administration of aspirin. There is a possibility of neurohumoral reaction being a responsible factor. The effect of aspirin on the blood crasis and on the hemostasis process favors the hemorrhagic character of the disturbance. Persons with ulcerous "terrain" should be dissuaded from using aspirin.

The Hypocholesterolemic and Plasma-Clearing Action of a New Heparinoid Extractive Free from Anticoagulant Effects. L. Sereno and A. D. Peruzy. Minerva med. 49:4195-4201 (Nov. 14) 1958 (In Italian) [Turin, Italy].

A new Italian heparinoid extractive free from anticoagulative effects, Ateroid, was given to 42 patients of both sexes with high serum cholesterol and lipoprotein levels. One group consisting of 20 patients who had patent organic lesions of the cardiovascular system had one or another of the following diseases: myocardial sclerosis, chronic coronary disease, or aortic or arteriosclerotic generalized lesions alone or associated with arterial hypertension. The other group of 16 patients did not have patent cardiovascular lesions but had a marked disorder of the lipid metabolism and were affected by one of the following conditions: xanthomatous obesity, xanthelasma, cholelithiasis, nephrosis, or essential hypertension. The drug was administered orally after meals to 37 patients in daily doses of 60 mg. divided into 6 equal tablets for a period of 30 to 50 days. Five patients received the drug intramuscularly in doses of 20 to 40 mg. a day for the same period of time.

Serum cholesterol levels decreased in patients with patent cardiovascular lesions from basal values of about 272 mg. per 100 cc. to about 240 mg. per 100 cc. after 20 days, and they reached about 255 mg. per 100 cc. after 30 days of drug therapy. Serum beta to alpha lipoprotein ratios decreased from basal values of about 4.95 to about 3.43 after 30 days of drug therapy. These values remained low in some patients and returned to the basal ones in the remainder after a prolonged period of observation. Similar results, although to a slighter extent, were observed in patients without patent cardiovascular lesions. Serum cholesterol levels decreased from basal values of about 307 mg. per 100 cc. to about 282 mg. per 100 cc. after 20 days and to about 243 mg. per 100 cc. after 30 days of chemotherapy. Serum beta to alpha lipoprotein ratios decreased from basal values of about 5.45 to about 4.44 after 30 days of drug therapy.

Ateroid thus exerted a similar hypocholesterolemic and plasma-clearing effect in both groups of patients, except that it lowered the beta to alpha lipoprotein values in the first group of patients by 31% and in the second group by only 18%. Both oral and intramuscular administration of Ateroid produced similar results. The drug was well tolerated and produced no side-effects.

Use of a Tranquilizing Agent (Hydroxyzine) with Prednisolone in the Control of Allergic Disorders. J. L. Fox. Ann. Allergy 16:674-677 (Nov.-Dec.) 1958 [St. Paul].

Corticosteroids administered in combination with tranquilizing agents have been reported superior to corticosteroid therapy alone in the management of nonallergic disorders influenced by anxiety. The study reported here was designed to test whether this type of adjunctive tranquilizer therapy is likewise superior to steroid therapy alone in the treatment of various allergic disorders. The study was restricted to patients with bronchial asthma, allergic rhinitis, urticaria, or seasonal hay fever, and included only those whose previous course suggested that short-term corticosteroid therapy was indicated. These criteria were fulfilled in a total of 67 patients, 11 of whom were children under 12 years of age. As individual patients were seen, they were arbitrarily assigned to one of 2 treatment groups: patients in one group received prednisolone together with a tranquilizing agent (hydroxyzine), while patients in the other group received only prednisolone. In order to achieve a high degree of objectivity in evaluating the response of these patients, the study was conducted under double-blind conditions.

Significantly better control of symptoms was achieved by the prednisolone-hydroxyzine combination than by prednisolone given alone. No significant side-reactions were observed in patients treated with the combination; on the other hand, it was necessary to discontinue therapy in 12% of the prednisolone-treated patients because of reactions to the drug. The combination of hydroxyzine with prednisolone appears from these results to offer advantages over corticosteroid therapy alone in the short-term symptomatic treatment of bronchial asthma and other allergic disorders.

On a New Synthetic Cortisonic Substance, Dexamethasone (16-alpha-methyl-9-alpha-fluoroprednisolone), in the Treatment of Rheumatoid Arthritis. A. Robecchi, V. Daneo, S. Di Vittorio and others. Minerva med. 49:4163-4171 (Nov. 10) 1958 (In Italian) [Turin, Italy].

The effect of dexamethasone (Decadron) was studied in 22 patients, 7 male and 15 female, between 26 and 69 years of age, with rheumatoid arthritis. Two patients had received no previous treatment with steroids, 16 had been treated previously with steroids but the treatment had been discontinued for at least one month, and 4 patients were being treated with other steroids when treatment with Decadron was begun. The diet of the patients was not changed. The initial dose of Decadron ranged from a minimum of 1.6 mg. per day in 5 patients to 3 mg. per day in 3 patients. Each daily dose was divided into 3 or 4 subdoses given every 8 or 6 hours per day respectively. Maintenance dose ranged from a minimum of 0.75 mg. per day to a maximum of 2 mg. per day. Decadron had a beneficial effect on all the general and local symptoms: the relief of symptoms was similar to that obtained in treatment with prednisone. Suspension of the treatment caused a regression in the improvement obtained. Subjective symptoms were checked mostly within the first few days of treatment, and some beneficial effect could be noticed within 24 hours. A sensation of well being, increased appetite, gain in strength, disappearance of fever when present, and decreased erythrocyte sedimentation rate followed the relief of subjective symptoms. The behavior of the erythrocyte sedimentation, however, was not always parallel to the symptomatic improvement, and for this reason the authors believe that the optimal dose should be established by taking into consideration mainly the clinical condition of the patient; with patients in very serious condition it is difficult to obtain and maintain normal erythrocyte sedimentation values. From the clinical point of view Decadron had a very good effect on 10 patients; though symptomatic relief and clinical recovery were not complete, it was possible to reclassify these patients as having less severe forms of the disease. The results obtained in the remaining 12 patients were good; it was not possible to transfer these patients to a different functional class, but a marked improvement in their general condition and functional capacity was obtained. Decadron had no significant side-effects. A comparative study on the effect of Decadron and of other steroids showed that the relationship between the effect of Decadron and that of prednisone stood in the proportion 1 to 9; this effect was 1 to 8 in the case of triamcinolone. In one patient the clinical effect obtained with 1.5 mg. of Decadron was far superior to the effect obtained with a combination of 4.5 mg. and 150 mg., respectively, of prednisone and phenylbutazone.

PATHOLOGY

Carcinoid of the Appendix with Total Invagination of the Organ. G. Capitolo. Minerva chir. 13:1269-1274 (Nov. 15) 1958 (In Italian) [Turin, Italy].

A male patient, 34 years of age, was operated on for subacute appendicitis. At operation, the cecum appeared hyperemic. The appendix was completely turned inside out, like a finger of a glove, in the lumen of the cecum; the tunica mucosa formed the external side of the appendix, whereas the tunica serosa formed the internal side of the organ. The mesenteriolum was also hyperemic and intruded with the invagination of the appendix. An unsuccessful attempt to reduce the appendix to the normal condition was followed by resection of the mesenteriolum. The appendix was resected through a circular incision in the wall of the cecum at the site of the invagination. At microscopic examination, the mucous surface was ulcerated and contained granulation tissue full of lymphocytes, plasma cells, and necrotic cells of other types. Cords and nodes of epithelium cells, each with a globular, hyperchromatic nucleus and with frequent karyokinesis, were found in the mucosa, submucosa, and tunica muscularis. A diffuse, reactive lymphohistocytic hyperplasia in the stroma was observed. The histological diagnosis was invagination of the appendix affected by epithelioid neoplastic cells, which had varying features between carcinoid and anaplastic carcinoma. The patient was discharged on the 8th postoperative day and has been well for 3 years since operation.

Coronary Heart Disease and Physical Activity of Work: Evidence of a National Necropsy Survey. J. N. Morris and M. D. Crawford. Brit. M. J. 2:1485-1496 (Dec. 20) 1958 [London].

This report is one of a series. It continues the study of coronary (ischemic) heart disease in relation to physical activity of work. The hypothesis was previously stated that men in physically active jobs have a lower incidence of coronary heart disease in middle age than men in physically inactive jobs. More important, the disease is not so severe in physically active workers. All departments of morbid anatomy in the hospitals of the National Health Service of Scotland, England, and Wales were invited to take part in a national autopsy survey during 1954-1956 by sending particulars of the naked-eye findings on the coronary arteries, the myocardium, and other specified items for a consecutive series of 25 males, aged 45 to 70 years, coming to autopsy. About 5,000 reports were received, made up in round numbers thus: 1,200 deaths from coronary heart disease, etc. (group A); 1,000 deaths from conditions with a specially high prevalence of coronary artery disease—for example, deaths caused by hypertension and its complications, deaths in diabetics, deaths from arterial disease in other sites (group B); and, the remainder, 2,800 deaths from miscellaneous conditions, their main causes having no particular association with coronary artery disease (group C).

Two types of ischemic myocardial fibrosis in the left ventricle and interventricular septum are described: (1) the large, discrete, often solitary patch which is probably the end-result of major and acute infarction and is associated particularly with occlusion in a main coronary artery (90 cases among the 3,800 noncoronary deaths); and (2) smaller, commonly multiple scars, the result probably of more chronic and less severe ischemia, and occurring in hearts showing usually smaller focal narrowings of coronary arteries or branches (290 cases). Cases were classified as "hypertensive" or "other." About half of the patients in group B and 10% of those in group C were thus regarded as hypertensive. The large healed infarcts (type 1 fibrosis) were found equally in hypertensive and other patients; focal myocardial fibrosis of type 2 was commoner in hypertensive patients than in those without record or evidence of hypertension.

The last occupation of each man was graded on a three-point scale, in terms of the physical activity the job typically involved, as "light," "active," or "heavy." On the evidence obtained, the authors feel that the general hypothesis may be restated in causal terms that physical activity of work is a protection against coronary (ischemic) heart disease. Men in physically active jobs have less coronary heart disease during middle age, what disease they have is less severe, and they develop it later than men in physically inactive jobs. Since there are suggestions of other connections between physical activity of work and cardiovascular disease of middle age, and multiplying evidence from laboratory experiment of the beneficial effects of exercise on relevant cardiovascular physiology and pathology, the speculation may be advanced that habitual physical activity is a general factor of cardiovascular health in middle age. In the present material the hearts of sedentary and light workers showed the pathology of the hearts of heavy workers 10 to 15 years older. Coronary heart disease among heavy workers, though less common, less severe, and occurring later than among light workers, is nevertheless common enough to constitute a major health problem.

Mucocutaneous-Ocular Syndrome with Intestinal Involvement: A Clinical and Pathological Study of Four Fatal Cases. J. Bøe, J. B. Dalgaard and D. Scott. Am. J. Med. 25:857-867 (Dec.) 1958 [New York].

The designation "mucocutaneous-ocular syndrome" is used as a general collective term to include Behcet's syndrome, severe erythema exudativum multiforme, and the Stevens-Johnson syndrome. Usually the respiratory tract or the central nervous system is affected, and involvement of the gastrointestinal tract is not infrequent but has rarely been reported in the literature. This prompted the authors to report the history of 4 middle-aged women with the mucocutaneous-ocular syndrome and involvement of the gastrointestinal tract who were admitted to medical department B and the Gade Institute of the University Hospital in Bergen, Norway, between 1955 and 1957. The duration of the disease varied from 8 months to 15 years; the course was markedly remittent, although progressive. In 2 patients the main lesions were in the large intestine, associated with a clinical picture of ulcerative colitis. In one patient the lesions were confined for the most part to the rectum, and in the other the histological examination revealed that the entire gastrointestinal tract was involved, although gastrointestinal symptoms were not noted at all. The microscopic findings were chiefly limited to moderate, nonspecific, inflammatory reactions surrounding capillaries and venules. Sigmoidoscopy will not suffice to separate these cases from ordinary ulcerative colitis, but history of exanthem, recurring stomatitis, anogenital ulcers, and involvement of the eyes may be diagnostic. The observations in 2 patients indicated impaired wound healing, which suggests caution in surgical intervention.

The Latex-Fixation Test and the Lupus Erythematosus Cell Test: Investigations on Their Diagnostic and Etiological Significance in Primary Chronic Polyarthritis. H. Braunsteiner, F. Egghart, F. Reinhardt and G. Wiedermann. Deutsche med. Wchnschr. 83:2168-2170 (Dec. 5) 1958 (In German) [Stuttgart, Germany].

According to Braunsteiner and associates, the development of the latex-fixation test by Singer and Plotz in 1956 represented a definite advance in the diagnosis of rheumatoid arthritis (primary chronic polyarthritis). The test resembles the hemagglutination test, but instead of sensitized sheep erythrocytes, polystyrene-latex particles are employed. Latex solution is added to a series of test tubes containing progressive dilutions of patient serum. The authors slightly modified the technique suggested by Singer and Plotz in that, after centrifugation, the test tubes are allowed to stand for 24 to 48 hours, instead of reading the test results at once, as was done by Singer and Plotz. This has the effect that some tubes with higher dilutions have more time for precipitation, and some tests that at first showed negative reactions become positive. The authors also mention the modification suggested by McCoy and associates, the so-called droplet test, which saves gamma globulin as well as time. Although McCoy claimed that this modification had the exactness of the original test, Braunsteiner and associates found that the results were less exact. They tabulate the results they obtained with their technique of the latex-fixation test in 429 patients, pointing out that the test was positive in 170 of 184 patients with rheumatoid arthritis. The percentage of negative reactions was much smaller than in Singer's material. Tests made with the articular fluid of patients with rheumatoid arthritis were positive whenever the serum test was positive.

In the second part of this report, which is concerned with the L. E.-cell test, the authors point out that the clinical differentiation of rheumatoid arthritis from other collagen diseases, particularly lupus erythematosus, is frequently not sharp or clear. Joint involvement is dominant in the symptomatology of the visceral form of lupus erythematosus, and patients with rheumatoid arthritis often show the same general symptoms as do those with lupus erythematosus. The authors comment on the L. E.-cell test and cite literature reports indicating that the incidence of positive outcome of that test in patients with rheumatoid arthritis varies widely. They performed the L. E.-cell test on 100 patients, of whom 53 had rheumatoid arthritis, 4 had lupus erythematosus, and 43 were controls with various disorders. The L. E.-cell test was completely negative in 52 of the 53 patients with rheumatoid arthritis; in the remaining patient only one L. E. cell was found among several thousand cells, whereas in the 4 patients with lupus erythematosus classical L. E. cells accounted for from 1 to 10% of the cells, and, in addition, transitional cells were found. The authors feel that this difference is sufficiently sharp that there should be no differential diagnostic difficulties. In the control cases the L. E.-cell test was always negative.

PHYSIOLOGY

Does Transfusion Citrate Cause Hemorrhage? W. G. Dixon. Am. Surgeon 24:818-821 (Nov.) 1958 [Baltimore].

To ascertain whether the wound oozing that is sometimes seen after multiple transfusions is caused by excessive citrate, dogs were given rapid intravenous injections of acid-citrate-dextrose solution (which is the anticoagulant used in transfusions), and clotting times, calcium levels, tetany, pulse rates, and blood pressures were observed. Acid-citrate-dextrose solution was used instead of blood, because it eliminated the hemolytic reaction of blood itself. In addition, the smaller amount decreased the danger of overloading the dog's blood volume. The acid-citrate-dextrose solution, as prepared in Transvuso Vac blood donor bottles, contained 120 cc. of 1.37% sodium citrate, 0.5% citric acid, 2.45% dextrose, and water. This was considered equivalent to 2 Gm. of disodium citrate in calculating doses. The acid-citrate-dextrose solution was rapidly dripped intravenously either into dogs anesthetized with Nembutal, to simulate an operating-room transfusion, or into conscious dogs to simulate the patient not under an anesthetic.

In 35 experiments transfusion of acid-citrate-dextrose solution did not cause hemorrhage. Only one of the anesthetized dogs showed possible wound oozing, although the blood of almost all the dogs failed to clot as the result of so much acid-citrate-dextrose solution. Cardiac arrest occurred 26 times in anesthetized dogs and tetany 9 times in conscious dogs. The 26 cardiac arrests occurred in 11 dogs, the heart being restarted with massage 15 times. Massage might have corrected more of the arrests, except that the arrest was used to terminate most of the experiments. In 28 determinations the amount of sodium citrate to cause cardiac arrest or tetany in dogs averaged 200 mg. per kilogram of body weight, or between 10 and 20 mg. per kilogram of body weight per minute of injection.

Further Studies on Cholesterol Levels in the Johns Hopkins Medical Students: The Effect of Stress at Examination. C. B. Thomas and E. A. Murphy. J. Chron. Dis. 8:661-668 (Dec.) 1958 [St. Louis].

The authors carried out serum cholesterol determinations on 52 Johns Hopkins medical students at admission to medical school (test 1), during the final anatomy examination which is generally considered to be a severe form of stress (test 2), and during a period of regular academic work (test 3). The mean serum cholesterol levels at tests 1 and 2 were significantly higher than those at test 3. The serum cholesterol levels of 2 additional persons, who had stress studies during the biochemistry examination rather than the anatomy examination, showed a similar pattern when the values obtained during the final biochemistry examination were compared with those obtained at test 3. For certain students test 3 fell close to the final biochemistry examination; the drop in the serum cholesterol level from test 2 to test 3 was less marked in those patients. The total eosinophil count was significantly lower at test 2 than at test 3. These findings are consistent with the hypothesis that stress, such as accompanies the first few weeks of medical school or important final examinations, is accompanied by a significant rise in the serum cholesterol level.

PUBLIC HEALTH

Relationship of Amount of Cigarette Smoking to Coronary Heart Disease Mortality Rates in Men. R. W. Buechley, R. M. Drake and L. Breslow. Circulation 18:1085-1090 (Dec.) 1958 [New York].

The authors report information on cigarette smoking and data concerning coronary heart disease in 2 California population groups. The first group consisted of 3,994 longshoremen who received a multiphasic screening examination and were followed for 5 years. They were divided into 2 classes: light or nonsmokers and heavy smokers. In the first 5 years of follow-up 78 died of coronary heart disease. Of the observed deaths, 42 occurred among light or nonsmokers, compared with an expected 84 according to California age-sex-specific death rates, and 36 occurred among heavy smokers, compared with an expected 35. Similar proportions of observed to expected were not found for deaths from any heart disease other than coronary. A retrospective case-control study, by questionnaire and interview, was made in the second population group, consisting of 116 men with coronary disease and 121 matched control persons. The 116 men reported a much higher mean amount of smoking, averaging about 16 cigarettes per day, than the 121 controls who averaged about 10 cigarettes per day.

The heterogeneity of populations, differing approaches, and manner of reporting make impossible a good estimation of the magnitude of the relationship between cigarette smoking and coronary heart disease. The authors abandoned their attempts to make such an estimate from a combination of studies by various workers. However, the extent of the relationship is generally indicated by the difference in death rate between nonsmokers and heavy smokers. These differences show a strong and consistent relationship between cigarette smoking and deaths from coronary heart disease, at least in men between the ages of 40 and 70 years. The difference in mortality between cigarette smokers and nonsmokers at different ages varies from 1 to 7 excess deaths from coronary heart disease per 1,000 men per year. Smoking rates in the United States are high, and death rates among patients with coronary heart disease are also high, in comparison with many other countries. Further studies of their relationship are needed.

Bacteriology of the Bedside Carafe. C. W. Walter, A. D. Rubenstein, R. B. Kundsin and M. A. Shilkret. New England J. Med. 259:1198-1202 (Dec. 18) 1958 [Boston].

Patients' complaints of unpalatable water at the bedside called attention to the potential hazard of this water as possible vehicle in cross infection in hospitals. In 24 Boston hospitals inspectors of the Massachusetts Department of Public Health selected a carafe at random from a bedside table for the accompanying bacteriologist. Coliform organisms were found in 21.7%, and staphylococci in 68.9% of the carafes sampled. Only 5 carafes out of 103 were sterile. The tap water in the 24 hospitals contained no coliform organisms or staphylococci. Fresh Boston tap water and clean ice made from it do not support bacterial growth. Direct contamination of the water in a vessel occurs each time it is sipped through a drinking tube. The residual water in the tube at the end of the sip drains back, carrying saliva. Bacteriological contamination also occurs readily in the carafes with dual-purpose lids. Residual liquid is returned to the carafe as the cup-shaped lid is inverted. The edge of the cup also carries organisms from the patient's lips when the cup is inserted into the neck of the carafe. Grossly unhygienic conditions were described in two-thirds of the carafes. Dead, partially decomposed insects were frequently seen. The walls of some carafes were slimy; gelatinous islands of algae and fungi floated in others. Most carafes had a stale odor.

In 3 of 6 hospitals where paper cups and glasses were used instead of carafes, the water was sterile. Contamination in the other 3 was attributed to filling the cups with stagnant water from the carboy-type water cooler. The material of which carafes are made is unsuitable for sanitization by heat. Fourteen of the institutions used carafes that were destroyed by hot water at 77 C (170 F) recommended for sanitizing dishes. None of the hospitals specified the technique of the supposed daily washing of the carafes, although 9 of the 24 claimed daily washing in a mechanical dishwasher. No hospital specified disinfection as a part of cleaning. Cross contamination by faulty identification of carafes or by mixing of the lids, when several were iced simultaneously, was common. Bacteria were transferred from the fingers of personnel to the carafe in several ways. The narrow mouth of the carafe and the dual-purpose lids were often wiped with the fingers under running water as a cleaning gesture. In a third of the hospitals surveyed, the utility room was used for processing of carafes; in most of these the work was accomplished in the same area where basins, bedpans, and urinals were cleaned. In half of the hospitals the diet kitchen was used.

Ice was exposed to hospital traffic in unprotected and even bacteriologically hazardous locations. Shovels and hoes used to remove ice from machines were dirty. In many hospitals food, fruit, and beverage bottles were stored on the ice. In 6 hospitals the ice dispensers were located in utility rooms within splashing distance of the bedpan hoppers. Faulty installation and maintenance of ice makers were common. Only half of the machines were located in a protected spot.

The program recommended for providing a safe supply of bedside water includes: proper installation and operation of ice-cube makers that are isolated from sources of bacteria shed by patients and personnel; automatic bagging of ice cubes and storage at temperature less than —6 C (20 F); dispensing of ice cubes from refrigerated dispensers with ice tongs; provision of carafes with wide mouths to facilitate cleaning, inspection, and filling; daily sanitization of carafes with heat; processing of carafes in the diet kitchen by personnel trained in food handling; and complete emptying and refilling of carafes from the tap each time they are serviced. Bedside water should be of a quality comparable to the drinking water supplied the community. Where melting ice is used, it must be dispensed from a solution of sodium hypochlorite.

BOOK REVIEWS

Modern Chemotherapy of Tuberculosis. By Roger S. Mitchell, B.A., M.D., F.A.C.P., and J. Carroll Bell, B.S., M.D., M.S. Foreword by William B. Tucker, M.D. Antibiotics monographs no. 11. Under editorial direction of Henry Welch, Ph.D. and Félix Marti-Ibáñez, M.D. Cloth. $4. Pp. 109, with illustrations. Medical Encyclopedia, Inc., 30 E. 60th St., New York 22. Distributors outside U. S. A.: Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

Since streptomycin became generally available in 1947, changes in the treatment of tuberculosis have come at an accelerated pace. This monograph summarizes the present status for the physician who wants to apply the new modalities of therapy. It discusses the three principal drugs (streptomycin, *p*-aminosalicylic acid, and isoniazid) in the treatment of tuberculosis from the standpoint of dosage and duration of therapy, with an important section on mode of action and pharmacology. The principal secondary drugs are similarly but more briefly discussed. The advantages and disadvantages of single-drug and multiple-drug treatment are outlined. The net result is a perspective on the therapy of tuberculosis as a whole. With so chronic a disease as tuberculosis the final determination of the result of a particular form of treatment must wait for many years. In the meantime, decisions must be made on the best evidence available. The monograph indicates where information is not yet definitive but presumptive, and states the results of the authors' experiences. Some of their assertions may be expected to be controversial.

In a general sense, tuberculosis has come to be treated as less "chronic" and more "acute"; however, the time is not yet at hand when tuberculosis may routinely be treated in the home. Treatment is now shared by the expert with the general practitioner and internist to an extent greater than ever before. For the physician who is called on to share in this obligation, this monograph will prove valuable. The text is enhanced by an extensive and comprehensive bibliography. The chapters include history, pharmacology, modes of action, dosage, regimens, drug resistance, modern chemotherapy, diseases and conditions with adverse effect, new and less used drugs, and results of antituberculous chemotherapy to date.

Therapeutic Exercise. Edited by Sidney Licht, M.D. Third volume of Physical Medicine Library. Cloth. $16. Pp. 893, with 204 illustrations. Elizabeth Licht, Publisher, 360 Fountain St., New Haven, Conn., 1958.

This large book was written by 35 different authors (12 are European and 1 is Canadian); it has 36 chapters and two appendixes. The first 18 chapters have to do with the basic principles of therapeutic exercise such as the motor unit, physiology of exercise and fatigue, mechanical anatomy of motion and posture, and structure and motions of the shoulder, hip, feet, and hands. Several chapters discuss the various types and uses of exercise and the apparatus required, especially in hydrotherapy. There are chapters on kinetic occupational therapy, testing of muscle strength, and other tests and measurements such as measurement of articular movement. One chapter is devoted to the controversial subject of "proprioceptive facilitation in therapeutic exercise."

The last 17 chapters concern the uses of exercise in disease conditions, including scoliosis; poliomyelitis; amputations; orthopedic conditions; foot disabilities; arthritis; multiple sclerosis; paraplegia; pulmonary, heart, and vascular disease; obstetrics; and orthoptics. There is also material on exercise for normal persons and an interesting and well-documented chapter on the history of the therapeutic use of exercise. Appendix 1 is a report of a study of the effect of brief isometric contractions on muscle, as compared to the more commonly used isotonic contractions which increase strength and endurance in muscle. Appendix 2 defines the terms used in therapeutic exercise which are not fully expanded in the text.

The book has some strong chapters and, as might be expected, some that are not particularly good. The chapters on physiology and anatomy are good, but they do not integrate the material with clinical usage to any great extent. Many basic physical principles are not given. This is not really a criticism of the book, but it indicates how voluminous the subject is. Some of the chapters by authors from abroad may be difficult to follow because their approach and terminology are at variance with those in the United States. The chapter on scoliosis is especially difficult, because this is a poorly understood and controversial subject in any country or language. The chapter on postural exercise is more philosophical discussion than presentation of specific material. The chapters which discuss the disease entities or conditions are good, and, in most instances, quite exhaustive.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

Therapeutic exercise implies knowledge of all motion and locomotion of the body, all basic physical and biological factors involved, and all the systems directly and indirectly related to production of energy and control. It is readily evident, therefore, that the subject cannot be adequately covered in one volume. However, as indicated by the editor, this is the largest single volume on the subject, and probably comes nearer to the goal than any other work published so far. It probably will not be used as a required text for the student of physical therapy because it is too advanced, and there is not enough material on some of the basic factors and techniques. However, it should be a valuable reference book for undergraduate students, physiatrists, and other interested physicians, and to a lesser degree for graduate physical therapists.

Sensitivity Reactions to Drugs: A Symposium Organized by the Council for International Organizations of Medical Sciences Established under the Joint Auspices of UNESCO and WHO. Edited by M. L. Rosenheim and R. Moulton. Assisted by S. Moeschlin and W. St. C. Symmers, Cloth. $7. Pp. 237, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

The symposium presented in this compact, meaty volume was organized by men from Great Britain, Belgium, France, Germany, Holland, Italy, and the United States. The 19 contributors and 5 participant observers are all investigators of one or more facets of the subject. Their fields include clinical medicine, chemistry, immunology, and hematology. In addition to a foreword and an introductory chapter, the book contains 17 chapters on hypersensitivity to drugs, each of which is followed by a discussion among the participants and a thorough list of references.

The first half of the book is devoted to discussions of changes in various blood elements (red blood cells, platelets, granulocytes, and bone marrow) due to allergic reactions caused by drugs. The last half of the book covers the following subjects: early detection of drug sensitivity; sensitivity reactions to antibiotics; nephelometric studies on the serums of patients sensitive to drugs; antibodies to drugs; the immunological character of humoral antibodies in drug allergy; chemical structure and pharmacodynamic action in relation to drug sensitivity; some general considerations on the diagnosis of the untoward effects of drugs; drug reactions linked with histamine release in man; tissue reactions produced by sensitivity to drugs; the occurrence of so-called collagen diseases systemically affecting the connective tissues, as a manifestation of sensitivity to drugs; and arteritis due to drugs. The subject index at the end is complete and accurate.

The quality of the material presented is not as variable as one might expect from the large number of participants. Most of the chapters are excellent; a few are not on a par with the others and one chapter contains conclusions based on a single case study. The discussions following each chapter are informal and at times irrelevant to the material presented. In general, this work is an excellent summary of the literature in an important and expanding field of medicine and a valuable book for the library of any physician, no matter what his field of special interest.

Economics of Mental Illness. By Rashi Fein. Joint Commission on Mental Illness and Health monograph series no. 2. Report to Staff Director, Jack R. Ewalt. Cloth. $3. Pp. 164. Basic Books, Inc., 59 Fourth Ave., New York 3, 1958.

The magnitude of the problem of mental health in terms of patients has been emphasized in recent years. In this volume the problem is approached from the standpoint of the cost of mental illness to the people of the United States—not just the expenses of hospitalization, medical care, and research, but also the money lost through the nonproductivity of the mentally ill. Admittedly, accurate figures are not available on some of these points, and estimates of such items as the amount paid in fees to general practitioners and internists by patients whose complaints are primarily psychological can be little more than speculative. It might be argued that it is not realistic to consider that all patients suffering from mental illness could be absorbed into the labor market and social order without a terrific impact on its basic structure, but recognizing these difficulties the author has attempted to present a fair estimate of the annual direct and indirect costs of mental illness which he conceives to be 3 billion dollars. The suggestion that from the economic standpoint alone it may be more profitable to increase the direct costs to provide better care and treatment for the initial admissions of the mentally ill seems logical when duration of disability is considered for patients whose illness becomes chronic. This little volume should be valuable reading for those who wish to consider not only the economic problem of the mentally ill but also the means of estimating the various factors which must be evaluated in assessing the costs of any illness.

Current Concepts of Positive Mental Health. By Marie Jahoda, Joint Commission on Mental Illness and Health monograph series no. 1. Report to Staff Director, Jack R. Ewalt. Cloth. $2.75. Pp. 136. Basic Books, Inc., 59 Fourth Ave., New York 3, 1958.

Since the Joint Commission on Mental Illness and Health was organized a few years ago under a grant of $1,500,000 from Congress, great expectations have arisen concerning its report. The Commission was designed to make a three-year study of the total mental health needs and resources of the United States and is now in its third year of operation. "Current Concepts of Positive Mental Health" represents the first phase of the total report. Approximately nine more volumes will be forthcoming, each dealing with a different aspect of the total study. The rather large sum of money to be spent in making the Commission's study, and the large number of people and organizations whose assistance was enlisted to carry it out, excited many criticisms of both its objectives and its methods. Physicians not involved in the study have frequently criticized the study on the grounds that there appeared to be a relative absence of psychiatric leadership in its actual operation. If this first monograph is representative of the entire report, this criticism will prove justified. The book consists of 119 pages of personal speculation by the author on the nature of mental health. It is a survey of a narrow segment of the literature on mental health. As the first volume of the Joint Commission's report, it is a huge disappointment. All the material presented was well known to most people in the field of mental health long before the Joint Commission began its study. The last chapter is an amendment to the report entitled "Viewpoint of a Clinician," by Walter E. Barton, M.D., a Boston psychiatrist. He takes issue with the author's view of mental health versus mental illness, but his criticism is a weak one and attacks only a minor fragment of the main issue.

Recent Advances in Cerebral Palsy. Edited by R. S. Illingworth, M.D., F.R.C.P., D.P.H., Professor of Child Health, University of Sheffield, Sheffield, England. With foreword by Norman B. Capon, M.D., F.R.C.P., F.R.C.O.G. [With appendix, Cerebral Palsy: Voluntary and Tax-supported Services in the United States, by Sherwood A. Messner, Director of Service, Medical and Scientific Department, United Cerebral Palsy Associates, Inc., of 24 pages.] Cloth. $10. Pp. 389, with 136 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W. 1, England, 1958.

Few subjects in medicine present as many and varied problems as does that of cerebral palsy. No one person can be an expert on all aspects of this disease; 14 specialists from the United States, England, and Australia were therefore asked to discuss the recent advances made toward meeting the total needs of the child with cerebral palsy and to decide where further investigation is needed. The result of their discussion is this authoritative treatise, which gives an accurate account of our present knowledge concerning the incidence; cause; pathology; the clinical signs by which to distinguish various types; methods of testing intelligence, speech, and hearing; drugs used in treating convulsions; and the orthopedic and neurosurgical procedures for preventing, correcting, and controlling the neuromuscular condition. There is a general agreement among the specialists that during the last decade advances have been made in these areas, but evaluating the methods of physical therapy or speech therapy is still a problem. As one author points out, it is "very difficult to determine how much of a child's apparent improvement after some months or years is due to treatment, and how much is due to the child's increased maturity." Dr. Illingsworth and his colleagues have described the recent advances in cerebral palsy and pointed out the areas which need further investigation. It behooves all those working with children with cerebral palsy to familiarize themselves with the contents of this book.

The Practice of Sanitation. By Edward Scott Hopkins, Principal Associate Engineer, Bureau Water Supply, Baltimore, and Wilmer Henry Schulze, Assistant Commissioner of Health, Sanitary Section, Baltimore City Health Department. Third edition. Cloth. $8. Pp. 487, with 141 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

This volume presents a clear, concise picture of sanitation. It is not loaded with unintelligible charts and graphs, and it covers all the significant details adequately. Any physician who may be asked about some local sanitation problem should by reading this book be able to orient himself on the matter quickly and thus be in a position to provide real help to the community. By the same token sanitarians, health officers, public health nurses, and even governmental officials who are trying to learn something about basic principles of sanitation should be helped greatly by these discussions. In this edition, the authors have wisely presented new approaches on such currently significant topics as food sanitation, air pollution, housing, rural and urban sewage disposal, stream pollution, insect control, and others of importance.

From the first chapter, in which is presented a stimulating panorama of the progress of sanitation down through the ages, to the last, which describes the establishment and accomplishment of a sanitary survey, the book is absorbing. The writing is refreshingly direct and simplified. At the end of each chapter is, in most instances, an extensive bibliography. Although not lavishly illustrated, the volume contains numerous drawings and photographs that provide additional useful information. As is pointed out in the foreword, there is no justification in this country for complacency about present sanitary practices in communities and industries. This volume provides desirable information about things that still need to be done.

The World Traveler's Medical Guide. By Richard Travis Atkins, M.D., and Jane McGlennon Atkins. Paper. $1.95. Pp. 399. Simon & Schuster, 630 Fifth Ave., Rockefeller Center, New York 20, 1958.

This volume deals with the medical aspects of travel in all parts of the world. Chapter 1 discusses medical problems related to travel by auto, train, ship, or plane; chapter 2 gives information on the required or recommended immunizations; chapter 3 furnishes useful information on such specific problems as water, milk, food, motion sickness, diarrhea, effect of altitude, and clothes to be worn; and chapter 4 discusses specific diseases and their nature. These chapters are followed by brief but adequate information as to what can be expected and what to do when confronted by a special health problem in any given country. Medical facilities in all areas, with names, addresses, and telephone numbers of English-speaking physicians, and locations of medical schools and hospitals are given. The "Guide" is unique because it deals exclusively with medical problems. According to the authors it is the first of its kind. The information given is adequate and authoritative, and the book is unhesitatingly recommended to the prospective traveler.

Physiology of Spinal Anesthesia. By Nicholas M. Greene, B.S., M.A., M.D., Professor of Anesthesiology and Lecturer in Pharmacology, Yale University School of Medicine, New Haven, Conn. With foreword by John Gillies, C.V.O., M.C., F.R.C.P.E., James Y. Simpson Reader in Anesthetics, University of Edinburgh, Edinburgh. Cloth. $6. Pp. 195, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

The author is to be congratulated for what should become a classic in the literature of anesthesiology. This book has long been needed. It discusses the physiological effects of spinal anesthesia relative to the nervous system, cardiovascular system, pulmonary ventilation and hemodynamics, adrenal functions, endocrine functions, metabolism, obstetric physiology, and gastrointestinal tract. It is well edited and printed on good paper. It is neat and concisely organized and has an extensive, carefully selected bibliography. One has a feeling that it was a labor of love which produced this truly outstanding textbook. It is strongly recommended to all individuals and libraries concerned with spinal anesthesia.

Treatment of Breast Tumors. By Robert S. Pollack, M.D., F.A.C.S., Clinical Instructor in Surgery, Stanford University School of Medicine, San Francisco. Cloth. $6. Pp. 147, with 63 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1958.

This comprehensive but brief volume is devoted to the treatment of breast tumors, including cystic mastitis. The system of classification used is simple and workable and avoids impractical detail. Diagnostic criteria are briefly discussed. The technical procedures of excisional biopsy and removal of benign tumors and other pathological processes are described. As would be expected the major portion of the book deals with various aspects of carcinoma. The importance of exploration of small tumors is stressed. The author presents his criteria for operability which are reasonably widely accepted. The practical difficulties confronting the surgeon in determining operability are well covered. Consideration is given to the indications for simple, modified radical, standard radical, and extended radical mastectomy. The procedures are illustrated. The chapters on irradiation list the indications for its use, and the methods employed are outlined. The limitations of irradiation in cancer of the breast are discussed. Additive and subtractive hormone therapy is well handled. The proper use of estrogens, androgens, and adrenocortica hormones is presented. Oophorectomy, adrenalec tomy, and hypophysectomy are evaluated as ad juncts to therapy. In controversial areas the autho presents opposing views, and an effort is made t arrive at fair and balanced conclusions. The bibli ography is extensive and up to date. The autho has presented a surprising amount of material i 142 pages. The brevity and readability of this worl recommend it as a good source of ready reference

Haematological Technique for Medical Laboratory Tech nicians and Medical Students. By E. M. Darmady, M.A M.D., F.R.C.P., Senior Pathologist, Portsmouth and Isle c Wight Area Pathological Service, Portsmouth, England, an S. G. T. Davenport, F.I.M.L.T., Chief Technician, Ports mouth and Isle of Wight Area Pathological Service. Secon edition. Cloth. $3.75. Pp. 244, with 27 illustrations. Grune Stratton, Inc., 381 Fourth Ave., New York 16; 15/16 Quee St., Mayfair, London, W. 1, England, 1958.

The authors, on the basis of practical experience describe the specific techniques for the usual bloo tests. The descriptions are adequate and are fol lowed by brief explanations of the fundamenta mechanism behind the disease process; this shoul be helpful to technicians who wish to understan the rationale of their work. In many cases, alter native methods are given. In chapter 18 a brief bu adequate account of the theory of errors in hema tological procedures and in medical statistics i given. The laboratory methods are those whic appear to be most commonly used in Britain, an the descriptions of the stained cells are based o the Romanowsky and Leishman techniques, al though the procedure for Wright's stain is als given. A short, selected bibliography follows eac section, and there is a glossary of commonly use terms. The book should prove adequate for its pur pose and should take its place among the best o the subject.

A History of Ophthalmology. By George E. Arrington Jr M.D. Foreword by Félix Martí-Ibáñez, M.D., Professor an Director of Department of History of Medicine, New Yor Medical College, Flower & Fifth Avenue Hospitals, Ne York. MD monographs on medical history number thre Under editorial direction of Félix Martí-Ibáñez, M.D. Clot $4. Pp. 174. MD Publications, Inc., 30 E. 60th St., Ne York 22, 1959.

This well-written book describes the importan events in the history of ophthalmology, not a isolated events but in relation to general historica developments. It is the author's contention tha with few notable exceptions, developments i ophthalmology are consequent to developments in religious, philosophical, ethical, and technical thought. The peculiar importance of vision in man's relationship to the external world makes such an approach particularly pertinent. Dr. Arrington states that in the past, because of this relationship, the eye was the meeting-ground of many disciplines including neurology, physiology, religion, and philosophy. In chapter 14, the author makes an almost impassioned appeal, which strikes a sympathetic note in this reviewer, that the ophthalmologist not lose himself in his techniques but view his specialty against an appropriate background of cultural knowledge. Furthermore, he emphasizes the importance of the individual in furthering the advances of the future and deplores the tendency in present society to depreciate the individual in favor of group or mass attitudes. At the end of the book are a chronological table showing advances in ophthalmology, an incomplete directory of ophthalmological periodicals, and a list of ophthalmological societies and associations. It is recommended reading for all ophthalmologists and medical historians.

Handbook of Balanced Anesthesia: Practical Techniques in Dentistry, Obstetrics and Surgery. By Sylvan M. Shane, Attending Anesthesiologist, Lutheran Hospital of Maryland, Baltimore. Cloth. $7.85. Pp. 272, with 11 illustrations. Lowry & Volz, 5701 Newbury St., Baltimore 9; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This book shows the author's tremendous enthusiasm for a specific technique and the remarkable extent of his experience with it. The book is well illustrated, neatly printed on good-quality paper, and written in a free, easy-flowing, pleasant style. However, one wonders about the title of the book, since in all fairness to the author the anesthesiologic method described is no more balanced than the thiopental–nitrous oxide–curare or narcotic–nitrous oxide–curare methods.

The author discusses clearly and concisely, with elements of enthusiasm and prejudice, his views on the methods and application of this technique in various fields. There is a rather large section pertaining to dentistry. The ancillary portion of the book is so brief as to weaken its value. It is recommended only to those who are interested in this technique, i. e., the nitrous oxide–cyclopropane–oxygen combinations in a semi-closed system. There can be little doubt that this is a vital and useful technique endorsed by the author, but the loose manner in which statements are made throughout the book would justify the use of this textbook by only those who have had large experience in anesthesiology. It is not recommended to trainees in anesthesiology–nurses or physicians. For the sake of completeness, it should be included in libraries as a reference to this specific technique.

Clinical Hæmatology in Medical Practice. By G. C. de Gruchy, M.D., F.R.A.C.P., M.R.C.P. With foreword by J. V. Dacie, Professor of Hæmatology in University of London, London. Cloth. $10. Pp. 620, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

The purpose of this book is to "bridge the gap between the inevitably short and incomplete descriptions of blood diseases found in text books of general medicine and the large comprehensive and heavily documented haematological reference books and monographs." The criticism against heavy documentation has been corrected, and the references for further reading show many contributions of British authors. The textual emphasis is on the diagnosis and clinical management of standard diseases involving the blood and blood-forming organs. Details of technique are not supplied, but enough data are given to help understand the results of laboratory examinations. Bone marrow is emphasized in connection with each disease, including photographs of tissue sections. A useful feature is a series of tables summarizing the data to be studied in investigating different diseases, or in tabulating other material of importance in connection with each syndrome (e. g., plasma clotting factors, laboratory tests in disorders of coagulation, and causes of thrombocytopenia). The book should be a useful quick reference for practitioners in the clinical management of their patients.

Clinical Neurosurgery. [Volume V] Proceedings of the Congress of Neurological Surgeons, Washington, D. C., 1957. [Robert G. Fisher, M.D., editor-in-chief.] Cloth. $8. Pp. 206, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

This volume is dedicated to Dr. Francis C. Grant of Philadelphia, who is the author of three of the papers. These papers, on gliomas in the posterior fossa in children, surgery of meningiomas at the base of the brain, and cordotomy, represent the observations of one of our most experienced neurosurgeons over a period of almost 40 years. His comments are to the point and of great value. The other papers on subdural collections of fluid in children by R. M. N. Crosby, dynamics of the cerebrospinal fluid by E. A. Bering, the treatment of hydrocephalus by shunting cerebrospinal fluid into the circulatory system by R. H. Pudenz, unilateral exophthalmos by D. D. Matson, treatment of involuntary movements by I. S. Cooper and G. J. Bravo, anesthesia for neurosurgical procedures by H. C. Slocum and H. R. Hansen, ocular signs of cerebral tumors by F. B. Walsh, and spinal nuclear amyotrophy by D. N. Buchanan are all well prepared and may be read with profit. This volume continues to maintain the high level of excellence characteristic of the four earlier ones. At the end are a list of members of the Congress and an index.

QUESTIONS AND ANSWERS

REACTIONS AFTER INJECTION OF TETANUS TOXOID

To the Editor:—*In the past year, three patients have developed delayed reactions to injections of tetanus toxoid. These reactions appeared between 5 and 10 days after the injection and were characterized by marked local redness, swelling, and itching with regional lymphadenopathy and, in at least one, some fever and polyarthritis. All subsided in one or two weeks, either spontaneously or after treatment with antihistamines and corticosteroids. They were clinically characteristic of serum sickness. The material used routinely for booster doses of tetanus toxoid is an alum-precipitated preparation produced by one of the leading biological manufacturers. Injections are withdrawn from multiple-dose vials, and other recipients of injections from the same vials have shown no reaction. The dose has been 0.5 cc. given intramuscularly (although inadvertent subcutaneous injection is possible). Careful checking makes it seem almost certain that tetanus antitoxin was not given through error, and in none of the patients was there a significant immediate reaction. Have similar delayed, presumably allergic, reactions been reported with the use of tetanus toxoid? Would a patient who had such a reaction be expected to have a similar or more severe one were he to receive tetanus toxoid at some future date?*

John E. Sweeney, M.D., Topeka, Kan.

Answer.—In the earlier period of tetanus toxoid prophylaxis, allergic reactions of variable degree were encountered. Continued efforts to use less allergenic mediums for the production of tetanus toxin, and therefore toxoid, together with techniques of purification have reduced the incidence of allergic reactions to tetanus toxoid to a statistically low figure. In the instances cited, the reactions were of the delayed serum sickness type. Presuming that no errors could be the source of difficulty (tetanus antitoxin instead of toxoid), it would be desirable to communicate with the manufacturers of the toxoid to determine the various materials used in its preparation. Sensitivity tests could be conducted with the various antecedent materials. The procedures recommended for this purpose are described in standard textbooks on allergy. In the event that the authenticity of the history, the sensitivity tests, or both indicate the existence of an altered response to one or more antecedent materials used in the preparation of the specific tetanus toxoid, avoidance of reactions at later dates could be effected by (1) avoidance of tetanus toxoid in the patients cited—periodic checks on the antibodies for tetanus could be made by collaboration with a reliable biological laboratory or by cooperation with the producer of the tetanus toxoid—and (2) use of another company's toxoid preceded by allergy tests to exclude sensitivity to the newly selected material. It is significant that a booster dose of 0.5 ml. was used in the three instances cited. In general, 0.1 ml. (injected subcutaneously, with a tuberculin syringe used for measurement and avoidance of a change of the needle used for drawing out the material from the stock bottle) is a satisfactory booster dose of tetanus toxoid (see Queries and Minor Notes, Tetanus Immunization, The Journal, April 30, 1955, page 1663).

ETHER CONVULSIONS

To the Editor:—*During operation on a 13-year-old boy under open drop anesthesia, the patient was seized with convulsions. The temperature prior to the operation was 100.5 F (38 C), and no measures were adopted to lower this temperature either preoperatively or during the operation prior to the convulsions. The patient was under light anesthesia at the onset of the convulsions, oxygen was ample, and the appendix had been uneventfully removed. Ice packs were applied. After intravenous administration of thiopental sodium, should the ether dose have been increased to reduce cerebral excitability or should the dose have been decreased because of a possible relationship to the convulsion itself?*

Norman Michael Canter, M.D., San Francisco.

Answer.—Under the conditions described, the ether dosage should not be increased nor decreased but the administration of the ether should be stopped immediately. Many theories exist to explain the cause of "ether" convulsions, but from every case described three factors emerge: (1) some form of inhalation anesthetic, usually ether, is used; (2) the temperature of the patient or his en-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

vironment is elevated; and (3) the patient has carbon dioxide retention. Knowledge of the causes of ether convulsions is still so inadequate that it is suggested that all three of these factors should be eliminated as soon as possible. With the convulsions controlled with intravenously given thiopental sodium, 100% oxygen administered, steps taken to ensure removal of excess carbon dioxide, and the patient cooled, there seems to be no good reason for giving more ether.

Ether has some unknown relationship to the convulsion, and merely to reduce the dose of ether may not eliminate whatever this relationship may be. There is no evidence that increasing the ether dosage reduces cerebral excitability in these patients. Owens and co-workers (*Anesthesiology* 18:53, 1957), using dogs with convulsions under ether anesthesia, found that increasing the depth of the anesthesia to the stage of cardiac intoxication had no effect on the abnormal electrical activity of the brain as seen on the electroencephalogram. Bowman (*Am. J. Surg.* 23:295, 1934) recorded a case in which several attempts to deepen the anesthesia in a patient with ether merely increased the severity of the convulsions. Several similar cases are recorded in the literature. Papper (*Bull. U. S. Army M. Dept.* [no. 84] p. 81, 1945) reported a case in which increasing the ether dose controlled the convulsions, but the patient was an afebrile healthy young man undergoing an elective operation. This case is atypical. The case herein described is typical in that the convulsions appeared late in the operation. If the anesthesia becomes too light to complete the operation, another small dose of thiopental sodium, and not ether, may be given. Should more muscular relaxation be necessary to complete closure of the peritoneum, a small dose of succinylcholine chloride may be used, but facilities for adequate artificial ventilation must be at hand.

HOOKWORM AND LARVA MIGRANS

To the Editor:—*Please give information on cat and dog hookworm infestation. Is this the same as larva migrans?*

Glenn T. Howard, M.D., Alice, Texas.

Answer.—Ancylostoma caninum and A. braziliense are the usual species of hookworms found in dogs and cats throughout the warm areas of the world. In northern localities in both America and Europe A. braziliense is largely replaced by A. caninum, and in Europe both species are largely replaced in dogs by Uncinaria stenocephala. Adult forms of A. caninum have been reported in man five times and A. braziliense less than 200 times. This suggests, in view of the prevalence of these two hookworms in areas where man goes barefoot, that he has a natural resistance to these two species. The larvae of these hookworms can penetrate the skin of man, but they usually go no further. The larvae of A. braziliense is largely responsible for creeping eruption or cutaneous larva migrans. The migration of these larvae intracutaneously produce serpiginous, erythematous, elevated, and sometimes vesicular lesions. The larvae migrate several centimeters a day, and the lesion extends along behind them. This migration continues from several weeks to several months until death of the larvae. The larvae of A. caninum and U. stenocephala usually do not migrate widely in the skin of man but die in the area of their original penetration, producing a localized, transient, papular eruption. The larvae of the human hookworms A. duodenale and Necator americanus and also of the nematode Strongyloides occasionally cause creeping eruption. The subcutaneous migration of fly maggots may be confused with these infections.

The existence of a large number of therapeutic agents argues against the efficacy of any of them. (Diethylcarbamazine and stibophen have been used systemically most widely, with variable success. Lowenthal (*Australian J. Dermat.* 2:171, 1954), in a statistical evaluation of chemotherapy, concluded that systemic therapy does not hasten the death of the larvae. The most satisfactory topical therapy consists in freezing the area in which the larva is currently migrating by an ethyl chloride spray. Prevention of human infection consists of avoiding skin contact with soils contaminated by dog and cat feces such as is found at bathing beaches, beneath houses, and in children's sand boxes. The latter should be covered when not in use. Hookworm-infected dogs and cats should be treated with tetrachloroethylene. Visceral larva migrans is caused by the migration through man's organs of the larvae of the dog and cat ascarides of the genus Toxocara.

ENLARGED COSTOCHONDRAL JOINTS

To the Editor:—*A biopsy specimen from a patient with enlarged costochondral joints showed normal cartilage. The joints have been infiltrated with both procaine and prednisone, with no relief. Enough pain is present so that it is hard for the patient to do his work. How can he be relieved?*

Dale R. South Jr., M.D., Troy, Ohio.

Answer.—Enlargement of the costochondral joints is usually localized to one or two ribs at the cartilaginous juncture of that rib with the sternum. No conservative plan of treatment has proved to be of any real value. Excision of the cartilaginous enlargement, together with about ½ in. of the end of the rib itself, is usually followed by complete relief. The cavity left after taking out this mass of cartilage and bone will fill with blood which will clot and organize and shortly become a firm fibrous mass which is not painful.

NICOTINIC ACID AND VISUAL SYMPTOMS

To the Editor:—*Could large doses of nicotinic acid cause an imbalance of vitamin absorption and thereby produce visual disturbance, or could such doses have a toxic effect on the retina? A 60-year-old man had, for two years, severe attacks of vertigo lasting one or two seconds and occurring every 4 to 12 weeks. Repeated physical examinations revealed no cause except the possibility of episodic cerebrovascular insufficiency, including that from stimulation of the carotid sinus. It was found, however, that the serum cholesterol level was elevated to about 265 to 300 mg.% and the fatty acid level was 584 mg.%. The elevation of the cholesterol level was confirmed on several occasions. On this basis, the patient was advised to take nicotinic acid. Small doses were given in July, 1958, and were increased to 3 Gm. daily after a few days and to 4.5 Gm. after six weeks because the serum cholesterol level remained elevated to 279 mg.%. In addition, he used a low-fat diet but consumed a liberal amount of lean meat, plenty of vegetables and fruit, and a vitamin supplement. Whatever fat was needed for cooking consisted of unsaturated fats (mostly corn oil). He lost about 7 kg. (15 lb.) in nine months and now weighs about 65 kg. (143 lb.); his height is 5 ft. 7 in. (170 cm.). On this regimen the serum cholesterol level had dropped to 221 mg.% by the middle of September and no attacks of vertigo had appeared in the preceding few months. An alarming symptom, however, had appeared: the patient, who had had myopia since youth but who had had good correction with glasses, could hardly read. He reported that print appeared "smudged." A competent ophthalmologist found that his eyegrounds were in excellent condition for a man his age and that there was no sign of glaucoma. His vision, corrected to 20/20 in each eye for years, could be corrected only to 20/30 in each eye, and the ophthalmologist found "relative central scotomata which extended about 10 degrees in both eyes." The patient stopped using nicotinic acid and took, on an empirical basis, 1,000 mcg. of vitamin B_{12} twice a week by injection and 25,000 units daily of vitamin A by mouth. On Oct. 1, the ophthalmologist found the eyegrounds normal as before. The vision, however, could be corrected to 20/20 in both eyes, and the subjective visual complaints had disappeared. Four weeks after nicotinic acid was withdrawn, the serum cholesterol level was again up to 330 mg.% in spite of the low-fat diet. Should this patient resume the use of nicotinic acid?*

Ludwig Gruenewald, M.D., Sheboygan, Wis.

Answer.—The transient "smudging" of print, some reduction in vision, and relative central scotomas do not suggest any clear-cut clinical entity, nor has an excess of nicotinic acid been reported as a cause of visual symptoms. It is suggested, therefore, that the patient's symptoms were only fortuitously related to the nicotinic acid therapy. They may have been due to circulatory disturbances of the occipital lobes. Impairment of the posterior cerebral circulation may, on rare occasions, cause central scotomas. Also, tobacco amblyopia (probably not related to nicotinic acid) may produce such symptoms as this patient had. It would be pertinent to know, therefore, if the patient smoked excessively. The foregoing case report was reviewed by a nutritionist; who pointed out that comparable amounts of nicotinic acid have been given to several hundred patients without untoward effect (Persons and others, *Circulation* 28:489, 1958, and Berge and others, *Circulation* 28:490, 1958). The doses of nicotinic acid used were, however, excessively large from a physiological point of view, and time has not permitted a definitive evaluation of such therapy. It is, therefore, important to have cases such as this on record. It may be of interest to the inquirer that there is a section in the *A. M. A. Archives of Ophthalmology* entitled Registry of Interesting Cases for the reporting of just such cases. Dr. W. B. Parsons of the Jackson Clinic, Madison, Wis., noted that visual symptoms had not occurred in 140 patients treated with nicotinic acid for hypercholesteremia except for one patient who had had transient blurring. Parsons suggested that the patient referred to in the question be treated again with nicotinic acid and control placebos to see whether the symptoms would recur.

URINE FOR CULTURE

To the Editor:—*Please supply details of a recently described method for culturing a female patient's urine which obviates the need for catheterization.*

M.D., New York.

Answer.—There are several methods of obtaining a urine culture from the female patient which obviate the need for catheterization, but none of these are practical. One such method is that of needle puncture of the bladder, using a needle introduced suprapubically into the full bladder in order to obtain a sterile specimen. This was done as a research project and would not be practical or safe for everyday use. Another technique is that of catching a mid-stream culture on a voided specimen. This is carried out as follows: The patient is given an extra amount of fluid to drink and 30 to 60 minutes later is placed on a bedpan and draped, as for sterile catheterization. The labia are then cleansed with soap and water, benzalkonium chloride, and dry sponges in succession, and this procedure is repeated three times to completely clean the vulva and urethral meatus. During this time, the labia are held apart to expose the urethral meatus and must continue to be held apart during the preparation and the voiding. After preparation, the patient is asked to void and the urine is caught during mid-stream in a sterile test tube. This technique also has the disadvantages that it requires elaborate preparation, may be embarrassing for the patient, and does not eliminate the possibility of contamination.

Clabaugh and Rhoads (*J. A. M. A.* 165:815-818 [Oct. 19] 1957) described a technique of catheterization which avoids the possibility of introducing bacteria into the bladder and also of false contamination of the catheterized specimen. This technique uses a large catheter which is advanced part way into the urethra, almost to the bladder neck, followed by a smaller catheter introduced within the large catheter and advanced completely into the bladder to obtain the specimen. This does away with any possible urethral contamination by the actual catheterizing tube. It is, however, cumbersome in the hands of ordinary hospital nurses. Recent studies indicating the frequency of bacterial contamination of the urinary tract from catheterization have led many physicians to fear catheterization and to avoid it when at all possible. This consultant believes that a properly conducted catheterization is not dangerous, and one should not hesitate to perform catheterization when there are specific indications for doing so.

PAINFUL CORNS

To the Editor:—*An item in* Science News Letter *(Jan. 4, 1958) states that injections of vitamin A palmitate under painful corns have been able to stop pain. Is this treatment recommended?*

M.D., Louisiana.

Answer.—The injection of an aqueous solution of synthetic vitamin A palmitate under painful corns cannot be recommended. Drummer, the podiatrist whose work was noted in the *Science News Letter*, wrote in the March, 1958, issue of the *Journal of the American Podiatry Association:* "Naturally no heloma [corn] can be permanently cured unless the cause is removed." The causative factor in most corns is enlargement of the head or base of one of the phalanges of the toe. Dr. Drummer, in his series of 21 cases, injected a local anesthetic into the site before injecting the vitamin A. Over the years, similar results have been obtained by injecting sclerosing materials, local anesthetics, corticosteroids, or sterile water into the area. In the September, 1958, issue of the *Journal of the American Podiatry Association*, Levy reported a controlled evaluation of the subdermal injection of corticosteroids. In his series, he found that 58.6% of the patients received relief from pain with no side-effects when he injected only the vehicle in which the corticosteroids were suspended. This compared with 42% of the patients receiving relief from pain, with side-effects in many cases, when the corticosteroids were given. He further stated: "There is some question whether the corticosteroids have produced any therapeutic effect that would not have been produced by supportive measures and the injection of the control solution." The only way to relieve pain from a corn is to remove the cause, use protective padding, and wear proper footgear.

Answer.—Vitamin A palmitate has been used in a few patients and results have been considered good, but this consultant cannot state definitely that these results were entirely due to the injections of this compound, because electrocoagulation was used as an adjunct. Simple injections of local anesthetic agents beneath the growth, followed by electrocoagulation, have also been used, and in some instances the results were about as good as with the use of vitamin A. It appears that the resultant damage to the growth can be accomplished by some simple injections of other chemicals in a similar manner.

EPINEPHRINE

To the Editor:—*A man in his fifth decade was recently treated for hives, with 0.3 cc. of a 1:1,000 solution of epinephrine subcutaneously, with no apparent effect. A few days later he was given 0.42 cc., again without effect. At this time the manufacturer replaced the supply of this agent with new stock. (The old stock was subsequently tested on another patient and was found to be potent.) On his third visit, the patient was given 0.6 cc. of epinephrine at 9:30 a. m. His pulse rate was 84 per minute before the administration and remained stable. At 10:00 a. m. he was given 0.45 cc. of epinephrine, followed in two minutes by another 0.45 cc. minims. He was observed closely for 30 minutes. There was no evidence of flushing, tremor, or increase in pulse. At 11:15 a. m., his pulse rate was 88 per minute and he had experienced no noticeable effects from the injection. The urticaria at this time had receded but was still visible. The patient gave the history of having taken 100 mg. of ACTH per day for several days in 1950 for iritis. Prior to the present illness, he had never been given epinephrine. Is this experience unusual? What is the connection, if any, between previous large doses of ACTH and refractoriness to epinephrine?* *James N. Dewane, M.D., Chicago*

Answer.—The injection of 0.5 to 1 mg. of epinephrine in normal persons is usually followed by a rise in systolic blood pressure, a fall in diastolic blood pressure, a rise in pulse rate, and, frequently, subjective feelings of anxiety; however, there are wide individual variations. In some persons no response occurs, while in others the response may reach alarming proportions. The differences undoubtedly depend to a large extent on the rate of absorption of the drug. This tends to be slow, due to the local vasoconstricting action of the drug; subcutaneous injections are more slowly and erratically absorbed than intramuscular injections. Therefore, while patients with certain conditions, such as myxedema, are said to be characterized by a relative tolerance to epinephrine, the normal variations are so wide that interpretation of the response under abnormal conditions is difficult. There is no reason to believe, however, that the previous large doses of ACTH could have influenced the response of the patient to epinephrine.

DEATHS DUE TO TETANUS ANTITOXIN

To the Editor:—*Please give statistics on the annual number of deaths caused by giving tetanus antitoxin. How many deaths occur annually from tetanus? Is it not true that many physicians refrain from giving tetanus antitoxin unless the injury occurs in a barn or other place where the chances of tetanus are great?*

M.D., California.

Answer.—Deaths from tetanus antitoxin administration are not tabulated as such but are included in the International Classification of Diseases, Injuries and Causes of Death under E 944—other complications of prophylactic inoculation. This title includes reactions and complications resulting from inoculation of a biological substance, including immune serum, for immunization or other prophylactic but not therapeutic purpose. It does not include reactions and complications after vaccination against smallpox and postimmunization jaundice and hepatitis. The published figures of deaths in this group are low—4 deaths in 1956, 14 in 1955, and 10 in 1954. According to the National Office of Vital Statistics, the deaths from tetanus for the period of 1952-1956 are as follows: 1952, 360; 1953, 337; 1954, 332; 1955, 265; and 1956, 246. These figures include tetanus neonatorum but exclude puerperal tetanus. In the absence of previous active immunization with tetanus toxoid, antitoxin should be given after injury in all instances where contaminated material may be imbedded in a wound. To confine such practice only when the injury "occurs in a barn" seems a rather hazardous procedure; Clostridium tetani has consistently been found not only in manured soil but also in street dust and, exceptionally, even in the dust of hospital operating rooms. The injection of antitoxin should be followed, in the next few weeks, by a full course of active immunization with toxoid, since tetanus might not develop for weeks or months after the wound has healed. If adequate immunization has been done four or five years before the injury, a more effective method of prevention consists in giving a booster injection of fluid toxoid within a few hours after the wound occurs.

PAROXYSMAL TACHYCARDIA

To the Editor:—*In a known case of paroxysmal auricular tachycardia, 20 cc. of 10% calcium gluconate was given intravenously with apparently prompt restoration to a normal sinus rhythm. If this should fail, would it be permissible to follow this promptly with an intravenous digitalizing dose of lanatoside C?*

Glenn T. Howard, M.D., Alice, Texas.

Answer.—There is experimental as well as clinical evidence that intravenous injection of calcium salts per se may precipitate as well as abolish arrhythmias due to ectopic impulse formation and may also suppress the activity of the primary pacemaker and cause cardiac arrest. Furthermore, cases are on record in which sudden death was ascribed to intravenous injection of calcium after digitalization. Although a potentiating effect of calcium and digitalis, suggested by these observations, has not yet been definitely established, the use of the two drugs in conjunction or in short succession seems to be associated with a great risk and should, therefore, be avoided.

HYPNOSIS MACHINE

To the Editor:—*It is said that a brain wave synchronizing machine, that will induce hypnosis, is available to the medical profession. Since the American Medical Association has accepted hypnosis, properly controlled, please comment on the use of this machine, especially in obstetrics.*

M.D., California.

Answer.—The brain wave synchronizer is an electronic instrument designed to induce various levels of hypnosis by subliminal and photic stimulation of the brain waves. The inventors, a clinician and an engineer, have developed a method for "driving" the alpha rhythm. The instrument can be used alone or combined with a tape recording of the therapist's induction and dehypnotization techniques. Easily followed directions enable proper use of the apparatus. The instrument definitely increases receptivity to suggestion and has been clinically tested on more than 2,500 subjects, including over 200 obstetric patients attending group hypnosis prenatal training classes. The apparatus induced light to deep hypnotic levels in over 90% of the subjects. Hypnotic response is more readily produced if a favorable "mental set" is created. Therefore, to some extent, the expectant attitude created by the structured situation enhances the hypnotic response, but about 30% of the subjects who had received no explanation or verbalization and who had no knowledge of what the brain wave synchronizer would do were hypnotized to various degrees ranging from light to deep states. The apparatus has remarkable potentialities for deepening a previously fixed hypnotic level and for facilitating and speeding up hypnotic induction, which often can be time-consuming, especially in refractory subjects. It also can help make labor and delivery a more gratifying experience by reducing discomfort and the need for excessive analgesia and anesthesia. Thus, the brain wave synchronizer has wide application to clinical and experimental hypnosis research. A distinct advantage is that no physical connections or attachments are placed on the patient. The unit weighs only 7 lb. A detailed scientific report will appear in the April 1959 issue of *The Journal of Clinical and Experimental Hypnosis.*

TETANUS AND DOG BITES

To the Editor:—*Since the tetanus bacillus is an anaerobe, is it possible that tetanus can be transmitted from a dog bite? In this locality, a number of physicians give antitetanic serum to all patients bitten by a dog. Would a physician be liable for a malpractice charge for omitting the immunization if, subsequent to a dog bite, a patient should develop tetanus due to a minor injury which may have escaped the patient's attention?* *M.D., California.*

Answer.—Reference is made to questions that have previously appeared in this section: "Tetanus After Human or Dog Bites" (*J. A. M. A.* 16:1445 [Aug. 16] 1947), "Human Bites" (*J. A. M. A.* 156:1297 [Nov. 27] 1954), and "Tetanus Protection Following Dog Bite" (*J. A. M. A.* 166:429 [Jan. 25] 1958). A clean dog bite would not require protection of the patient against tetanus. A bite contaminated with dirt would validate specific prophylaxis (tetanus toxoid, tetanus antitoxin, or both, as indicated). Spaeth (*Nebraska M. J.* 41:224, 1956) gives indications for these. In general, the literature on tetanus makes no specific reference to the disease after dog bites. If tetanus should develop later from some other minor, undetected injury, it is not likely that the physician would be held guilty of neglect. However, to preclude such a situation, it would be desirable to inject a booster dose of tetanus toxoid provided (1) adequate basal protection with tetanus toxoid exists, (2) a booster dose has not been given recently, and (3) there is no epidemic of poliomyelitis (danger of paralytogenic effect of an injection if undetected viremia with poliomyelitis virus exists). In the absence of a significantly contaminated wound, if basal immunity against tetanus does not exist, tetanus antitoxin with its multiple potential complications would not be indicated. The general trend of thought among physicians responsible for the treatment of dog bites has been to avoid antitetanic serum in the presence of dog bites. Major emphasis has been directed to the prevention of rabies.

PSORIASIS

To the Editor:—*A 76-year-old patient developed about a dozen lesions on his legs and a fine rash on his hands which, though it could hardly be seen, could be felt. All the lesions itched intensely. When the condition was definitely diagnosed as psoriasis, triamcinolone was given and there was an immediate improvement, with the rash on the hands completely disappearing. The dosage of 4 mg. four times daily was gradually reduced to 2 mg. twice daily. Is there any reason why the present dosage should not be continued, and is there a prospect of the patient getting perfectly well?*

Howard M. Cooper, M.D., Rutherford, N. J.

Answer.—There is no very satisfactory treatment for psoriasis, nor can one give a prognosis with any certainty. Psoriasis may occur at any age. The course of the condition may be brief or last for many years. Therapeutic measures, intelligently used, often minimize the problem. Among topical remedies, the tars, ammoniated mercury, and such keratolytic agents as salicylic acid in various combinations have stood the test of time. Ultraviolet light may also have a beneficial effect in some cases. The use of steroids, such as triamcinolone, should be reserved for so-called psoriatic cripples and should be used for short periods only, for the steroids are not curative—they merely serve to control the acuteness of the lesions. Prolonged use of these drugs is attended by well-known risks, which hardly seems justified for a condition of no greater severity than the one described.

PREGNANCY AND LUPUS ERYTHEMATOSUS

To the Editor:—*A patient in her last trimester of pregnancy has had serious recurrent attacks of generalized lupus erythematosus. During the last acute exacerbation six months ago, she received large doses of prednisone; this dosage has gradually been reduced. She has had no cortisone derivative for the past two months, and her condition is fairly good, with no specific symptoms or complaints. What can be expected during and after delivery? Will there be any effects on the baby?* *M.D., Montana.*

Answer.—In all probability, the delivery will proceed normally. According to Haserick (*A. M. A. Arch. Dermat. & Syph.* 75:706, 1957), there were seven normal deliveries in eight pregnancies in a group of 165 patients with systemic lupus erythematosus. This is in contrast to the presteroid era reported on by Ellis and Bereston (*A. M. A. Arch. Dermat. & Syph.* 65:170, 1952), in which there was a 30% fetal mortality. The child should be normal, since systemic lupus erythematosus is not a familial or congenital disease. The prednisone administered early in the pregnancy or just prior to its inception should not prove deleterious to the infant. There is a difference of opinion among dermatologists as to the future care of such patients. The mother should be given clinical and laboratory surveillance. Friedman and Rutherford (*Obst. & Gynec.* 8:601, 1956) stated that the disease often improves during pregnancy but reverts to its prepregnancy state usually within two months post partum. If the patient remains afebrile and clinically well after gestation and there is no laboratory evidence of activity, active treatment should be withheld. Corticosteroid therapy is of suppressive value only, and therefore its use should be reserved for the treatment of signs and symptoms of this disease. It is doubtful if there is any logic in treating subclinical systemic lupus erythematosus as one would treat latent syphilis. Avoidance of sunshine, adequate rest, and maintenance of strength and weight should be recommended.

TUBERCULOSIS CONTROL

To the Editor:—*A question has arisen in connection with a revision of the tuberculosis control program in Wyoming. It is planned to abandon a sanatorium located in an isolated area and to build, in effect, another sanatorium in a city for the care of patients with tuberculosis. It has seemed that the current trends in therapy were in the direction of treating tuberculous patients in general hospitals near their homes rather than grouping them together in a location necessitating a separation from their families. Have the newer trends in therapy changed the thinking on this score? Can any qualified chest surgeon perform the required operations, or is this a more narrowly specialized field?*

Lloyd R. Evans, M.D., Laramie, Wyo.

Answer.—The trend in the United States is against the care of patients with tuberculosis in isolated institutions and toward urban locations for tuberculosis hospitals. Many general hospitals operated by larger counties have tuberculosis units for the care of residents of those counties. The same is true of hospitals operated by large cities. Proximity to general hospitals is essential for the provision of all special services, especially thoracic surgery. The sanatorium concept has given way to the hospital concept in the care of such patients. The new therapies have brought this about. Conversion of sputum occurs sooner, operations are performed often and early, and the duration of the patients' stay is lessened. Not many private general hospitals provide a tuberculosis unit or even welcome individual patients for long-term care. While desirable, this development still lies in the future. In general, chest surgery is done by thoracic sur geons, and their services are available in practicall all centers of population, not merely the large centers. Some general surgeons have had trainin in thoracic surgery and are competent in this field

GRANULOMA ANNULARE

To the Editor:—*A 13-year-old boy has typic granuloma annulare lesions on the dorsum of h right hand. This has been unsuccessfully treate with ultraviolet light. There has been a hesitatio to recommend radiation for this so-called benig lesion. Would streptomycin be of benefit? Wh other methods of approach are there to th problem?*

David K. Wagner, M.D., Santa Fe, N. Mex.

Answer.—Granuloma annulare is a capricio entity responding to different modalities in differe cases. Streptomycin may or may not be effectiv but its toxicity is much greater than that of x-radi tion and it is also more unpredictable. Such a dr should be used as a last resort. The first thing to is to examine a biopsy specimen. This procedu would confirm or disprove the diagnosis, since t histopathological architecture of this dermatosis characteristic. This maneuver is followed in ma instances by disappearance of the lesions of gran loma annulare. If this should fail, x-ray thera would be recommended. In the dosage and qua ties, with proper shielding, used by the derm tologist, the radiation does not damage the ski shorten life, or cause leukemia or genetic mut tions. However, if the physician or the patient st fears this modality, freezing with solid carb dioxide or carbon dioxide "slush" would be reco mended. There is no end of other methods th have been suggested, including the subcutaneo injection of hydrocortisone, intramuscular injectio of bismuth subsalicylate, and use of antimalar drugs, sulfonamides, and ultraviolet light.

URETERAL OBSTRUCTION

To the Editor:—*What happens to the human ki ney if a ureter is tied off?*

Len H. Andrus, M.D., King City, Calif.

Answer.—If a ureter is tied off, the kidney pr tically always becomes hydronephrotic and pain in varying degrees. Perhaps half of such kidne become infected, requiring subsequent surgical tention. At times, the pain in the tied-off kidn is not pinpointed in the postoperative recove period but disappears, only to recur when uri begins to trickle through the ligated ureter and t kidney begins to function partially. If both uret are inadvertently tied off, the absence of urine i tiates an immediate investigation usually resu ing in fairly rapid deligation of the ureters.

PREVENTION OF INJURIES IN COLLEGE ATHLETICS

Augustus Thorndike, M.D., Cambridge, Mass.

The records of 14,375 contestants in organized college athletics over a period of 17 years, embracing 36,050,885 practice-periods or games, showed 3,453 injuries severe enough to exclude the player from one or more subsequent practice or game sessions. This high incidence of 24% indicates the need for insisting on the player's "bill of rights" which is here stated. It includes good coaching, good equipment, and good medical care. The medical care includes a thorough preseason examination, the presence of a physician on the playing field, and due respect for his authority. A case history illustrates the prolonged disability and permanent residual damage done by ill-advised treatment of athletic injuries. Responsibility for diagnosis and treatment of athletic injuries should not be imposed on coaches and trainers but assumed and duly discharged by the physician.

THERE APPEARS to be general agreement that the incidence of injury in the United States is too high. Industry has reduced the incidence of industrial accidents markedly by a continuing educational and training program among its plant supervisors. Highway safety engineers have so far been unsuccessful in reducing the accident and death rate among our motoring public. The true incidence of sports injuries is not known for lack of accurate statistical data. Were this incidence known, something would be done about making our athletes, our coaches, trainers, and team physicians, the sports rules committees, and the sports equipment manufacturers more conscious of their responsibility in providing more safety measures. Our experience with the incidence of sports injuries is presented in table 1.[1]

In a period of 22 years this demonstrates the great increase in sports participation at our college. Considering that the intramural program this winter included 52 hockey games, 113 basketball games, and 152 squash racquet team matches, one realizes that student participation in exercise activities is high. In all sports this program averages 2,400 individual students, more than 50% of college enrollment. In varsity, junior varsity, and freshman sports, an estimated additional 1,700 of the college enrollment should be included. In other words, about 76% of our college student body is participating in organized sports.

In table 2 an attempt has been made to analyze the incidence of injury in 17 academic years (fall of 1936 through spring of 1954) by the number of exposures (practice or game sessions). I am not cer-

tain just what one can derive from this computation. In recording injuries, only those injuries are recorded that prevent a player from participating in one or more practice or game sessions. However, 3,453 injuries among 14,375 contestants represents a high incidence, namely 24%.

Table 1.—*Total Number of Athletes in Organized Sports in Harvard College from Fall, 1932, to Spring, 1954*

Season	1932-1937	1937-1912	1942-1947	1947-1954*	Totals
Fall	3,271	2,477	703	6,485	12,936
Winter†	1,235	1,662	280	8,895	12,072
Spring	2,112	2,720	445	7,670	12,947
Total	6,618	6,859	1,428	23,050	37,955

*The last period is for seven academic years rather than five. Since 1947-1948 the varsity and junior varsity football participants have been averaged.

†The figures for winter sports include only hockey and winter track, the only major sports in that season until 1937, when swimming and basketball were made major sports.

Any program for prevention starts with the individual player, who is entitled to his "Bill of Rights."[2] These are as follows:

(1) Good Coaching. This has practically been realized. The coach who teaches unsportsmanlike tactics to win at any price is almost extinct. Almost all coaches today are competent instructors in the technical aspects of the game, ignorance of which greatly increases the incidence and severity of injuries.

(2) Good Equipment. This, too, can easily be achieved. The equipment manufacturers take their responsibilities very seriously and are continually modifying and improving the various types of armor worn in contact sport. The problem lies in the false economy of using worn out, outmoded, or ill-fitting gear. The outfitting of a team is no place for penny pinching.

(3) Good Medical Care—which has three aspects:

First—a thorough preseason history and physical examination. This is the most important single factor in the prevention of injuries. A considerable number of the tragedies which occur every year are due to medical conditions such as heart disease, hypertension, and diabetes which were not recognized and usually constitute contraindications to participation in contact sport. For many years at Harvard, loss of function of any of one paired set of organs has also been regarded as contraindication for participation in body contact sports. This rule produces an annual crop of unhappy young men who seem to have played for years in high school with one testis, kidney, or eye, but we have made no exceptions. Other less potentially dangerous sports are available, and no game is worth the risk of blindness, death, or castration.

Another important aspect of the preseason examination, particularly in high schools and preparatory schools, is the proper matching of players. Boys grow at different rates. Some at 15 have mature and well-coordinated musculoskeletal systems. Others are small and soft, having barely entered the wondrous years of adolescence, and still others are large-boned, skinny, and uncoordinated, being in a period of rapid bone growth, with barely compensated nerves and muscles.

To mix these types on a team is to look for trouble. This is an area for cooperation between coach and doctor. Well-matched teams are much safer and much more fun for all concerned.

Second—A doctor should be present on the playing field at every scrimmage and game. To leave to a trainer or coach such decisions as whether an injured player should continue play or be removed, whether he should be carried or walk off the field is to gamble with the player's future with the cards stacked against him.

Third—A doctor's authority in matters medical should be absolute and unquestioned. This principle is the measure of a good coach. Almost all coaches today are happy to leave medical decisions to the medical profession. They have enough difficult decisions and problems as it is.

Granted that this "bill of rights" has been fulfilled, injuries will still occur. Fortunately the very great majority are minor, and fall into the category of contusions, strains, and sprains.
